The tendency to become tobacco-sick is not found in all soils. The above cropping tests were repeated on another tobacco soil at the Connecticut tobacco substation located at Windsor and in this instance there were no important differences in effects of the various crops on the yields of tobacco. It is well known that some lands have grown tobacco continuously for more than a half century without any loss of productiveness. There are also some lands on which tobacco has long been grown with satisfactory results in rotation with wheat, clover, timothy, and corn. On the other hand, the

FIG. 236.—Tobacco growing under exactly the same conditions as that shown in Figure 235 except that rye is grown as a winter cover crop each year. Note the small and uneven growth of the plants. Legumes and a number of other crops when used in the rotation may produce the same sort of injury. This injury, however, does not occur in all soils

tobacco-sick condition has been observed on sandy, sandy loam, and heavy loam types of soil and in various tobacco-growing sections.

Another important fact about the brown root-rot disease is that seasonal conditions may greatly modify the effects of the cropping system. On a fine sandy loam soil in southern Maryland hairy vetch as a winter catch crop has practically doubled the yield of tobacco in some years, whereas in other years the yield of tobacco has been considerably less than where no catch crop has been used. Similar results have been observed with rye and timothy as winter cover crops. The greatest depressing effect of these crops on the yield of tobacco usually occurs in wet seasons.

About the only simple remedy for the brown root rot known at the present time consists in resting the land for a year or longer, thus allowing the weeds to grow. It is a surprising fact that for tobacco culture on many soils no combination of crops in the various rotations which have been tried equals an alternation of tobacco and weeds. It appears, however, that one of the essential features of this plan is to allow the soil to remain undisturbed for a time. The exact function of the weeds which ordinarily grow under these circumstances has not been determined. It seems certain that the weeds at least produce no harmful effect on the tobacco, such as is apt to occur from a number of our ordinary farm crops when grown in the rotation.

W. W. Garner.

## TOBACCO Markets Show Cigarettes in Growing Favor

Tobacco habits change. Twenty-five or thirty years ago cigarette smokers were often referred to as "cigarette fiends." To-day the fiends are so far in the majority that the appellation is discreetly omitted. At that time it was no uncommon thing for boys to learn to chew tobacco, whereas to-day the cigarette claims their attention. The cigar, which for centuries has been the aristocrat of the tobacco world, only with difficulty maintains its high position, while the humble and unpretentious pipe continues to be the companion of the rich and the solace of the poor. Snuffing is no longer the chosen habit of royalty, but in perverted form has its addicts among the laboring classes, especially the colored population.

Changes in tobacco-consuming habits have a deeper significance than as mere expressions of popular fancy; they effect economic changes of great importance among the growers of tobacco to an extent which is little understood by the average tobacco consumer. The changes that have occurred in tobacco-consuming habits during the past 25 years are indicated in Figure 237.

In its work of estimating the acreage, production, and value of the tobacco crop of the United States, the department finds it necessary to give careful study to the various types of tobacco produced and to treat each type as a separate crop

### Public Ignorant of Tobacco Culture

To the vast majority of tobacco users tobacco is a sealed book so far as a knowledge of the characteristics, methods of culture, mode of curing, and manufacturing qualities of the tobacco of different sections is concerned. Perhaps no other important crop is so little understood by the consumers, and yet few other products of the soil are so widely used. That is not surprising when it is considered that hundreds of thousands of dollars are spent annually in advertising the virtues of the manufactured product, with rarely a mention of the history of the tobacco itself. Advertisements do not call attention to the back-bending labor of transferring the tender plants from seed bed to the field, the cultivation, the frequent suckering, the frequent and highly disagreeable task of searching each leaf for worms, or the days and nights of ceaseless vigil in tending fires during the curing of the crop, where heat is applied. Much less do they refer to the tedious labor of stripping the tobacco and tying the leaves into hands before sending to market.

Tobacco is raised on a commercial scale in 18 States. In most of these States the production is highly localized.

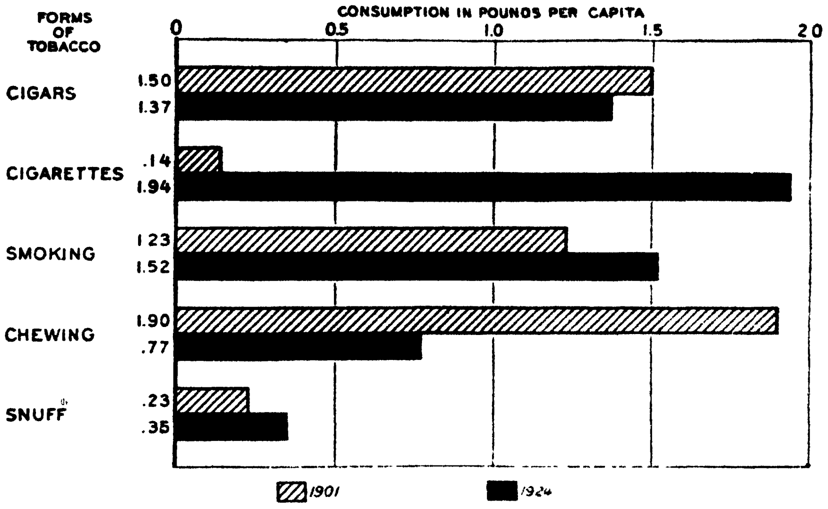

FIG. 237.—Changes in the per capita consumption of tobacco in the United States from 1901 to 1924. The most notable change during the quarter century has been the increased consumption of tobacco in the form of cigarettes

Twenty-nine types of tobacco are recognized in the official classification of American-grown tobacco published by the department, divided into six classes: These types are flue cured, comprising four types of tobacco cured in airtight barns by heat from large galvanized-iron flues extending under the hanging tobacco, fire-cured, comprising four types cured in the smoke of open wood fires; air-cured, including five types in which the tobacco is cured by the free circulation of air, no artificial heat being applied. The foregoing groups include all tobacco except that used in the manufacture of cigars. Cigar tobacco is all air-cured and is divided into three groups—filler, binder, and wrapper.

Tobacco as a crop is extremely sensitive to slight variations in soil and climate. It is found, therefore, that soils suited to one type of tobacco will seldom prove suitable for some other type. The result of this has been the localization of tobacco production into definite, well recognized "type districts," in which distinctive curing methods combined with soil and climate have evolved types of leaf peculiar to those districts, and adapted to different manufacturing needs. For instance, it was found that the light, sandy soils of southern Virginia, the Carolinas, and parts of Georgia and Florida produce a light, aromatic tobacco which when cured in heat but without smoke, possessed a bright yellow color. This is our most important cigarette tobacco and besides entering into all or nearly all of our cigarette blends is sold in enormous quantities to Great Britain, China, and other foreign countries. A generation ago, when tobacco chewing was popular and cigarette smoking less popular than it now is, bright flue-cured tobacco was used for plug, fillers, and wrappers.

### Aroma of American Leaf Unequaled

Efforts have been made in many foreign countries to duplicate the flue-cured tobacco of this country, and while in some of them, notably in China, it has been found possible to duplicate the American product in appearance, the aroma which distinguishes the American leaf and makes it so popular has never been equaled elsewhere.

The dark fired types of tobacco differ widely from the flue-cured in their soil requirements, appearance, method of curing, and the uses to which they are put. In contrast with the relatively small, thin leaves of flue-cured, those of the dark fired types are very large, drooping, heavy, and gummy. It is generally true that heavy, dark soils produce heavy, dark tobacco. Dark fired tobacco is produced on the red clay soils south of the James River in Virginia and on the loams of western Kentucky and Tennessee, a section commonly known as the "Black Patch." When harvested, the stalks are hung on sticks suspended tier upon tier on the poles of large curing barns. Curing is effected by the aid of slow oak or chestnut wood fires which are kept going for as much as two weeks. Curing by this method is a fine art and the care and skill of the farmer during this critical period have a very direct bearing on the quality of his product.

The result of this combination of type, soil, and method of curing is a heavy-bodied leaf of a rich mahogany-brown color, of silky, oily texture, and possessing a creosotic odor imparted by the smoke.

Dark fired tobacco has long been an important item in our foreign trade. It is used abroad for cheap cigars, smoking, chewing, and snuff. Its use in this country is limited. Small quantities have been used in the manufacture of cheap cigars, which find a sale among immigrants, particularly those from southern Europe. Some is used for plug wrappers. Its greatest use is in the manufacture of snuff.

### Dark Fired Market Reduced

Foreign countries are finding it possible to produce similar tobacco, and this fact together with a world-wide tendency among consumers to turn to cigarettes, has greatly reduced the market for dark fired tobacco in recent years. Prices paid to growers have become unremunerative, therefore, and production has fallen off.

The principal type of tobacco in the air-cured group is Burley. It was developed in southern Ohio and in the bluegrass section of Kentucky, and owing to its superior qualities for a variety of manufacturing purposes the demand for it has been very great and the production has spread back into the mountains of southern Kentucky, West Virginia, Virginia, North Carolina, Tennessee, along the Ohio river in Indiana and across Missouri. The greatest production is in Kentucky, Tennessee, and Ohio. It appears to thrive best on well-drained limestone and shale soils.

The harvested tobacco is hung in open barns and remains there until thoroughly cured. Colors range from various shades of yellow to dark red, and the uses to which various grades are put depend primarily upon the "body" of the leaf and the color. When the increasing manufacture of cigarettes began to absorb the flue-cured tobacco, manufacturers of chewing tobacco turned to Burley for their supply of leaf. For this use Burley proved ideal, owing to its mild character and its extraordinary capacity for absorbing the sweetening sauces used. Within the past 15 years Burley has become an important cigarette type, and, in addition, most of the smoking tobacco on the market is made from this type.

FIG. 238.—Harvesting tobacco in southern Maryland

Production of Burley tobacco has reached enormous proportions, more than 300,000,000 pounds of the leaf having been produced in 1926, but there are indications now that supply has exceeded demand.

Other air-cured types are Green River, a snuff and export type, one-sucker, used for chewing and export, sun-cured, a chewing type, and Maryland export. The latter type dates back to early colonial days and is a cigarette and export type.

### Cigar Type Distribution

Cigar types have a wide geographic distribution and cover a wide range of qualities and characteristics. For the most part they are produced under open field conditions according to the methods used in tobacco types already referred to. The finest cigar-wrapper tobacco produced in this country is grown under artificial shade in the Connecticut Valley and in a small area of Georgia and Florida. The principal producing districts are the Connecticut Valley, Pennsylvania, the Miami Valley of Ohio and Indiana, and Wisconsin.

All of these types of tobacco are reported upon individually, as may be seen by consulting the statistical summary in the Yearbook, where the acreage, yield per acre, production, price per pound paid to growers, and the farm value for each type in each State are shown for 1925 and 1926. In addition, the department issues a weekly summary of prices paid at representative markets in several important districts, showing the high, low, and average prices of different grades of tobacco, such as wrapper grades, filler grades, etc.

The importance of tobacco is indicated by the fact that the production of all types in 1926 is estimated at 1,323,388,000 pounds, with an estimated return to the growers of $245,113,000. An unusual feature connected with tobacco is the fact that the Government derives a greater revenue from the manufactured product than the growers receive for their crop. The farm value of tobacco in 1925 was $234,253,000; the taxes on manufactured tobacco collected during the fiscal year 1925 amounted to $345,247,210.96.

CHARLES E. GAGE.

## TOMATOES for Canning Now Standardized

The development of definite grades for canning tomatoes promises to eliminate the confusion now caused by the use of loose terms in contracts. There is a growing sentiment among both growers and canners that is favorable to the adoption of more definite specifications. Heretofore contracts have almost invariably called for "sound red ripe tomatoes." On first consideration this specification would seem anything but vague but, as a matter of fact, neither grower nor canner expects strict conformity to the requirement. As a practical matter the contract term means one thing when prices are high and something very different when prices are low. Such an arrangement inevitably results in general dissatisfaction.

The desire for definite uniform grades goes beyond the necessity of improving business relations by the clarification of contract terms. Canners have made a practice of paying a uniform price for all tomatoes which they were willing to accept. In a general way this price was based on the average quality of receipts. Obviously, such a practice has operated to penalize the best growers to help the poorest. High-quality tomatoes are not only canned at a minimum cost but also produce a high-grade manufactured product. Such stock should command a premium, and a proper recognition of this principle will result in better production methods and better handling practices.

In 1923 the United States Department of Agriculture undertook the task of formulating the necessary grades. The study was indorsed by representative canners and growers. Briefly, the problem was to devise grades which would properly recognize variations in commercial value and at the same time be simple enough to be practical in actual operations. After three seasons of investigations the department recommended grades which seem to meet these requirements.

### Basis for Sampling Provided

The United States grades provide a basis for sampling at the cannery. The grower does not sort the tomatoes into two grades but delivers all usable stock, leaving only the culls in the field. At the factory each load is examined by inspectors to determine the percentages of each grade. A premium is paid for the U. S. No. 1 grade, but the grower is docked for culls.

During the 1926 season the first official inspection of canning tomatoes was tried in an experimental way and with considerable success. The following method was pursued: The inspector selected several baskets of tomatoes from different parts of the load. These were dumped upon a sorting table and classified into No. 1's, No. 2's, and culls. Payment for each load was made on the basis of these results, which were entered upon a certificate provided for that purpose.

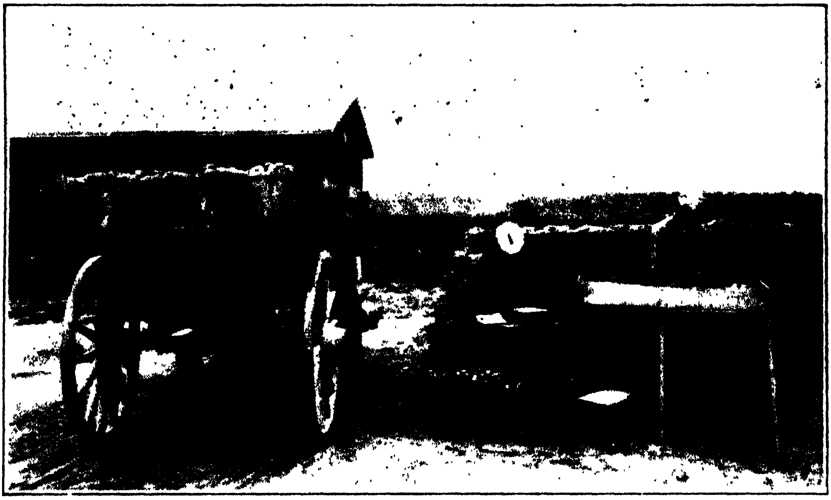

FIG. 239.—Inspecting canning tomatoes on the basis of United States grades

A study of inspection certificates shows a wide range of quality, from 10 per cent of U. S. No. 1 and 39 per cent of culls in the poorest load to 77 per cent of U. S. No. 1 and no culls in the best load. The price paid for the best load was 27 cents per 20-quart hamper, whereas that of the poorest load was only 15 cents per hamper.

The quality of canning tomatoes may be greatly improved by more careful attention to harvesting practices. The principal factors affecting grade are decay, ripeness, and color. Decay is difficult to prevent, but the degree of ripeness and color may be controlled to a considerable extent by the grower.

Grades for canning stock constitute a new venture in fruit and vegetable standardization. Certainly the progressive grower should recognize the advantage of trading on a basis which gives proper recognition to variations in quality. The real success of the United

States grades will depend primarily upon the willingness of the canners to pay a suitable premium for U. S. No. 1 tomatoes, thus giving the grower a real inducement to produce the desirable stock necessary for a superior finished product.

W. E. Lewis.

## TOMATO Varieties Developed for Wilt Resistance

The new tomato varieties, Marvana, Marvelosa, Marglobe, and Norduke, have been develepode by hybdridization and selection in the United States Department of Agriculture. The first three have been distributed for trial the past two years; the last, for several years.

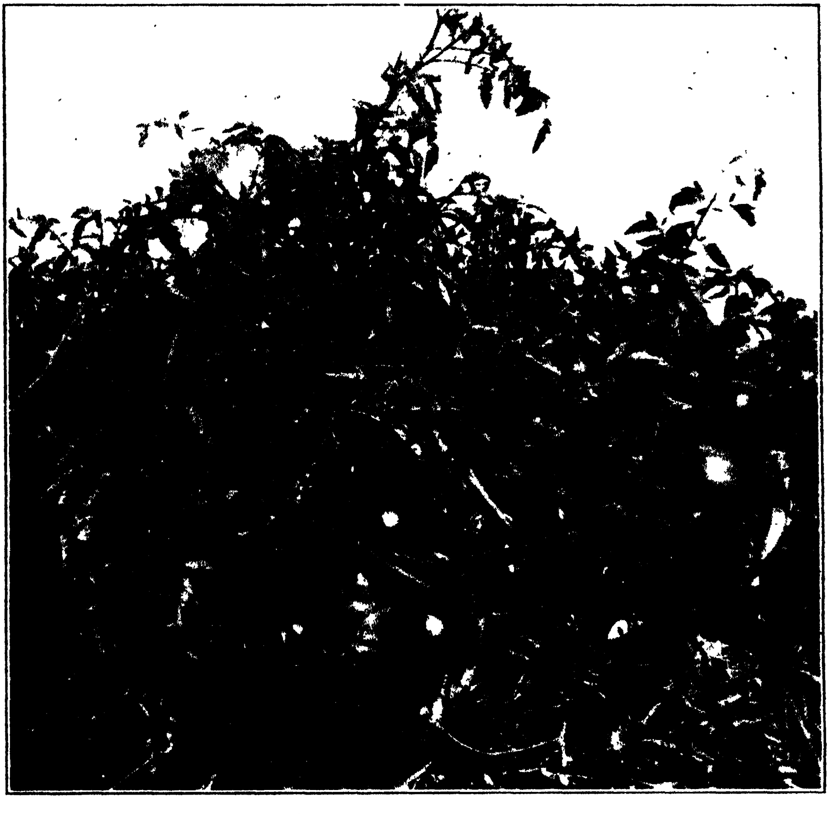

Fig. 240.—Marvana plant, showing type of foliage and fruit. Grown on heavily wilt infested soil

These varieties are highly resistant to Fusarium wilt and somewhat resistant to early blight, Septoria leaf spot, and leaf mold. Moreover their fruits are resistant to nail-head rust and puffiness, two frequent causes of heavy loss in tomato-trucking regions of the South.

Marvana (fig. 240) is a first-early red-fruited variety. It resembles Earliana in earliness, in size, and shape of fruits, and in type of foliage but its fruits are usually smoother, more crimson and slightly less acid and its foliage a little heavier, denser, and more resistant to drought and blights. In the department fields it has been fully as early and productive as Earliana.

Marvana was developed from a cross between Marvel and Earliana. It has inherited much of its vigor and disease resistance and a little of its color and smoothness of fruit from Marvel, yet closely resembles Earliana in its small leaflets and spreading habit of vine.

### A First Early Variety

Marvana is distinctly a first-early variety. It usually sets fruits freely and produces a good early crop, but its fruits are not as large and meaty as those of the best second-early varieties. It has given good results in both greenhouse and field and is worthy of trial wherever early fruits bring a high price.

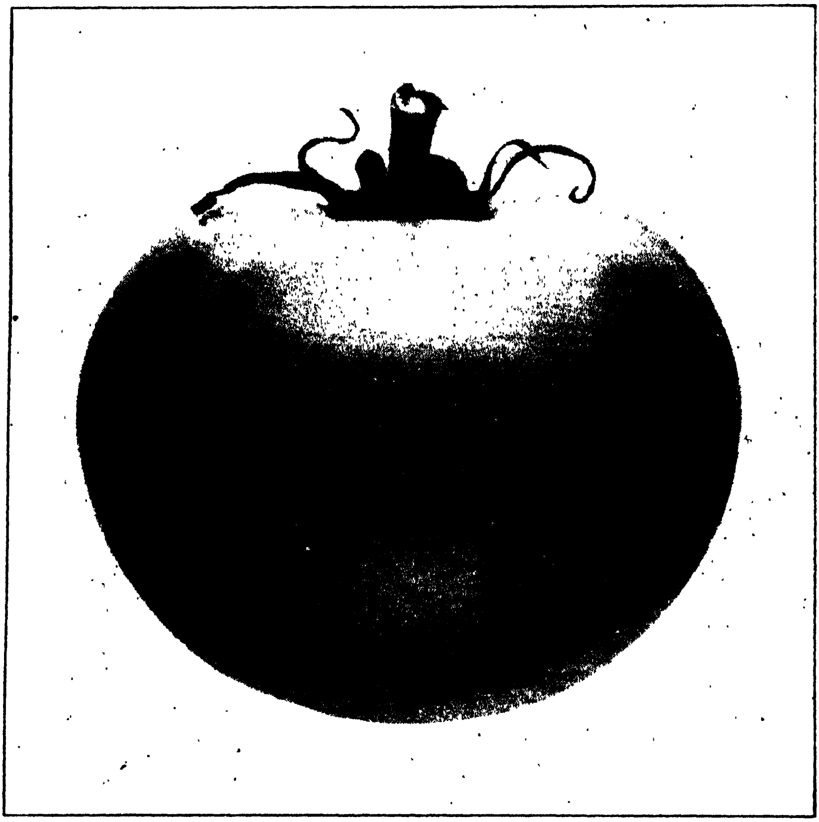

FIG. 241.—Typical Marvelosa fruit. Natural size

Marvelosa is a second-early pink-fruited variety. It produces about the same quantity and type of foliage as other second-early varieties, such as John Baer and Bonny Best, and under favorable conditions matures a good crop of medium large, smooth, meaty globular fruits. Fig. 241.) The fruits ripen uniformly and are very smooth even around the stem end. It is approximately as early as Globe.

Marvelosa originated from a cross between Ponderosa and Marvel. It possesses the pink appearance and transparent skin of the Ponderosa fruits and the vitality and disease resistance of the Marvel vine.

Marvelosa is suitable for trucking and forcing. It is in use in some of the trucking regions of the South and in many greenhouses in the Middle West where the trade favors pink fruits.

Marglobe is a second-early red-fruited variety. Its plants are medium large, erect and well covered with foliage which shades the fruits, enhances development of red pigment and eliminates much sun scald in hot weather. The fruits (fig. 242) are large, smooth, globular, meaty, almost coreless, and deep scarlet in color. They ripen uniformly even at the stem end, resist cracking well, and maintain a good quality throughout the picking season. Moreover they can be held for a considerable time without spoilage.

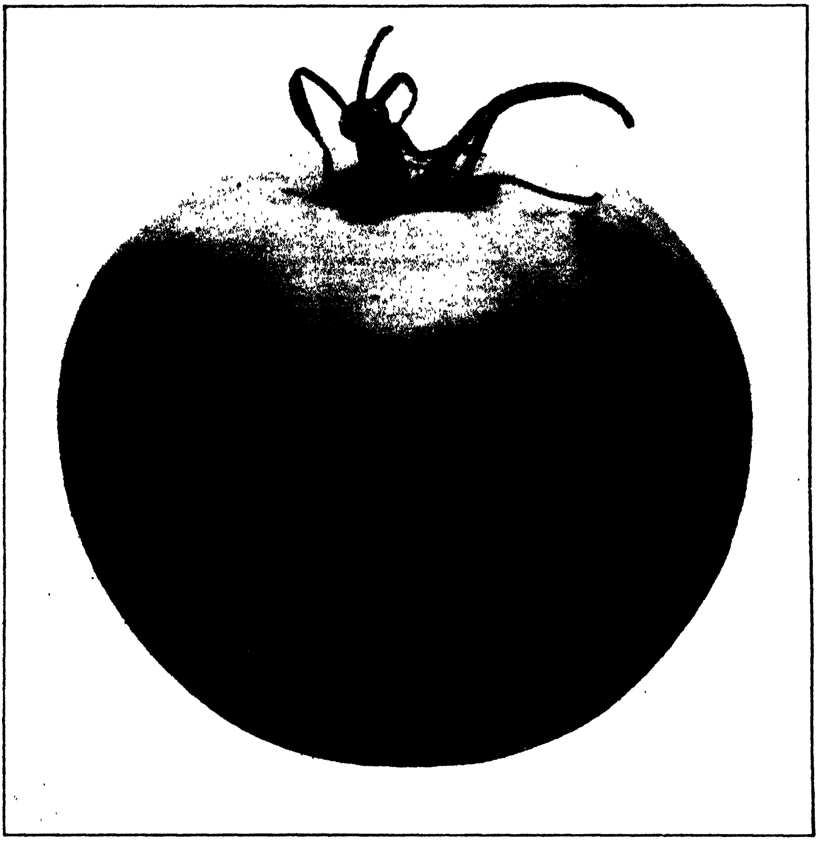

FIG. 242.—Typical Marglobe fruit. Natural size

## Free Fruit-Setting Habit

Marglobe has a very free fruit-setting habit, even under conditions in which most late varieties make excessive vine growth. In the department's fields single plants have not uncommonly borne from 80 to 125 good-sized fruits at one time. Moreover the plants keep setting fruits at the tips of the branches, which results in a continuous succession of pickings throughout a relatively long bearing period.

Marglobe was developed from a cross between Globe and Marvel. It surpasses Globe in earliness and is similar to it in size and shape of fruits, but closely resembles Marvel in vigor, type of vine, and resistance to diseases.

Marglobe is well adapted for trucking and canning. Its earliness favors its adoption in canning regions of Northern States where frosts and short seasons are common. Its heavy fruit-setting habit also fits it for many localities where prolonged heat or rainy weather often causes late varieties to go to vine. In some places it may serve a dual purpose by providing a few early pickings for use in the fresh state in the cities and several late pickings for manufacture at the local canneries. Although this practice is commonly used in some localities the varieties grown have a shorter bearing period and usually produce a poor quality of fruit after midseason. Because of its earliness and quality of fruit Marglobe also offers, in many places, possibilities of increasing the length of the canning and pulping season.

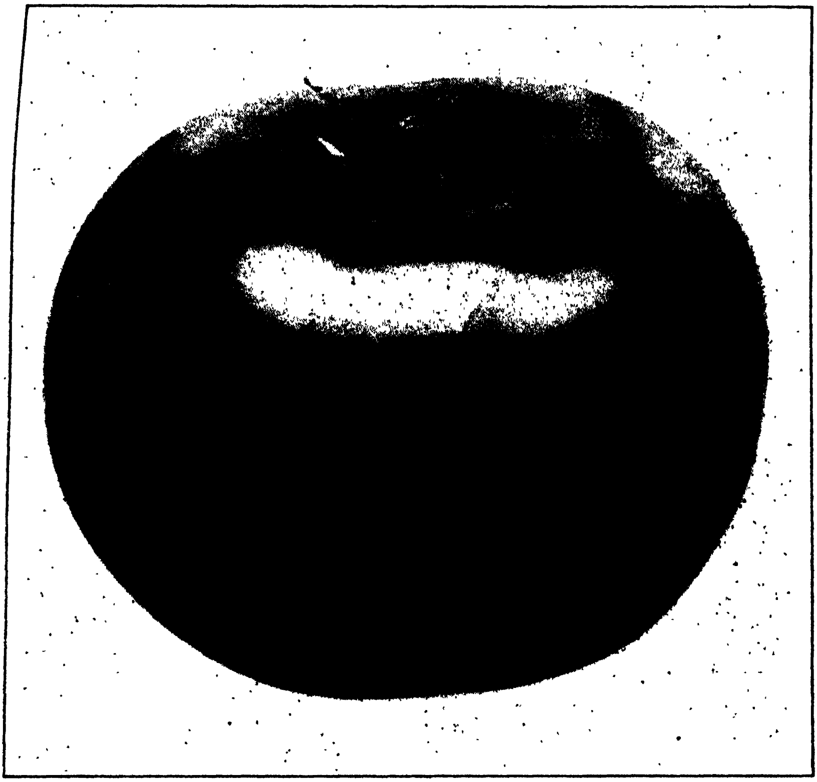

FIG. 243.—An average Norduke fruit. Natural size

On fertile soils favorably supplied with moisture Marglobe usually produces heavy yields of large fruits; on dry soils, however, it is not always able to produce large fruits because of the number set. From a $3\frac{1}{2}$-acre field of Marglobe at the Arlington Experimental Farm, Rossyln, Va., 22 tons of excellent fruit per acre was picked in 1925, which is approximately seven times the average yield for the State. Quite as large yields were obtained by a number of others who made a test of this variety on good soil.

Norduke is a large, late, red-fruited canning variety of the Stone type. Its plants are large, erect, and somewhat dense. Their branches remain upright longer than those of most other varieties, possibly because of their woody stems, but are ultimately drawn down by the weight of the fruit. The fruits (fig. 243) are large, smooth, oblate, fairly meaty, and comparatively free from cracks. A few are also somewhat shouldered at the stem end—a character by which the fruits of this variety may be distinguished from those of Stone and other varieties of this type.

### Has High Resistance

Norduke was developed from a cross between Norton and Duke of York (selection from Buckeye State) but is more like Norton in size, shape, and quality of fruit. It excels both parents in resistance to Fusarium wilt and Septoria leaf spot.

Norduke withstands drought better than most other varieties and usually produces good crops on rather dry or moderately moist or fairly sandy soils but is not well adapted to wet soils. Although not adapted to as wide a range of conditions as Marglobe, it has given good results in most States and is gradually increasing in use in the canning regions of the East, Middle West, and Pacific coast. On the Arlington Experiment Farm it usually produces from 10 to 12 tons of excellent fruit per acre.

FRED J. PRITCHARD.

## TON-Litter Aim Improves Hog Raising Methods

Not many years ago the term "drove" was in common usage when hogs were collected from farms and started for market on foot. Nowadays, shipments of hogs are referred to as truck loads or car lots.

Similarly, the weights of litters of pigs at marketing age are being measured to-day in terms different from those of the old days. Formerly, in feeding out hogs for market, large litters were commented upon as they are to-day for size, uniformity, and the number of pigs they contained, but the weights of the hogs were specified in pounds. To-day, the aggregate weight of the litter sometimes exceeds a ton and there has developed much popular interest in the so-called ton-litter movement, which has led to this result.

The idea was conceived in 1921 by James R. Wiley, extension animal husbandman, of Purdue University. The production of a single litter of pigs weighing a ton when 180 days old seemed a practical goal for the swine grower.

Projects were begun under the name of the Hoosier Ton-Litter Club, and during 1922 there were successfully produced in Indiana 36 litters of pigs which met this qualification when 180 days old. Considerable publicity followed this accomplishment and each succeeding year has seen the idea spread to other States until the term "ton litter" is now well understood wherever animal husbandry is taught and hog competitions are held.

FIG. 244.—A large litter of uniform, vigorous pigs underlies success in producing ton litters

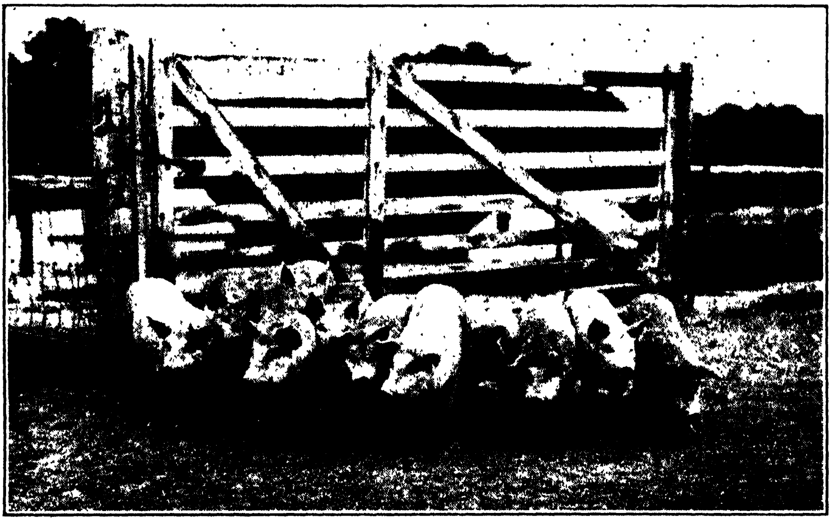

FIG. 245.—Rapid growth during the growing stage is essential for successful ton litters

In 1925 approximately 1,500 litters in 28 States were entered in trials for the goal, and while nearly half failed there were 767 officially certified as having qualified as ton litters, including 7 litters weighing well over 2 tons apiece.

The ton-litter movement is proving to be a valuable lesson to the hog industry, not so much by teaching farmers how to produce a given bulk of pork, but by furnishing them a practical means of measuring their methods of breeding, feeding, and management. Knowledge gained in the experience of ton-litter production, applied to the herd, results in the establishment of breeding animals of desirable type and quality, the elimination of sows which are not good mothers, and the production of pigs which feed out well and uniformly from birth to finish weights.

Ton-litter success has been gauged to a considerable degree by the individual merit of the sows in the various breeds. Purebred pigs, without regard to any particular breed, have formed most of the litters which have been fed successfully to ton weights.

FIG. 246.—Ton-litter pigs furnish desirable weights and attractive carcasses for the market

Examination of the records of the feeds used in the production of ton litters shows that no stereotyped feed mixtures are required and no uncommon or unusual feeds are necessary.

No stimulation is necessary other than that contained in the usual grains, protein supplements, and mineral feeds combined with the exercise, good air, and sunlight usually recommended in swine husbandry.

Ability to recognize a good prospective sow for ton-litter success, and to carry through the details of management to a successful conclusion is an indication that the principles of swine production are well in hand.

The application of this knowledge to all litters and breeding animals in a herd, season after season, regardless of the final weight of litters, will insure satisfactory returns for the owner.

S. S. BUCKLEY.

### TRACTOR Farming in Dry Regions Has Advantages

The topography of a certain dry-land wheat area in eastern Oregon ranges from nearly level to rolling slopes and is broken by canyons. The soil varies from a sandy loam to a silt loam type and is free from loose surface stones. Rainfall is very limited and dry-farming methods are well established. The prevailing farm practice is to clean-cultivate the land one year and follow with a crop of grain the succeeding year.

In these wheat areas land values and yields per acre are relatively low while the wages of hired labor are relatively high, so that farmers have found it to their advantage, within proper limits, to spread their work over a maximum acreage which may return little to the acre, but much for the labor and capital expended. Farms are large, adapted to the use of large-size machinery, and require large amounts of power. To provide this power many farmers have turned to the farm tractor.

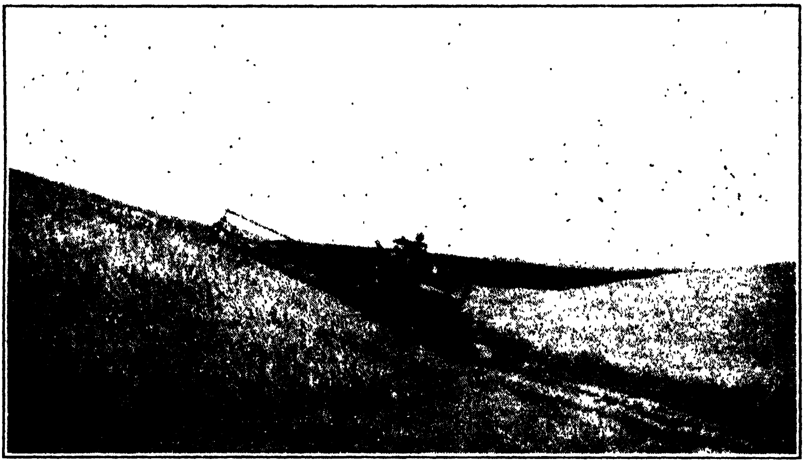

FIG. 247.—Harvesting and threshing wheat with a 16-foot cutter-bar combine drawn by a 40-horsepower tractor. An outfit of this size will cut and thresh about 35 acres per day

Many of these tractor owners have tried various types of tractors, some of which were not suited to their conditions. The consensus of opinion appears to be that the crawler or track-laying type is most satisfactory. This type is built low to the ground, does not overturn easily, and is well adapted for use on the rolling slopes on these farms.

### Forty-Horsepower Size Popular

Tractors of from 10 to 50 drawbar horsepower have been tried out in this area, but those of the 40-drawbar horsepower size are most in favor, especially on the larger farms. These tractors of the larger sizes are used for pulling the larger-sized combines and for fitting the land with large units of tillage equipment. (Fig. 247.)

Large units of power afforded by the tractor permit these farmers to do large amounts of work at rush periods and to do the work more nearly at the proper time. In plowing, farmers with tractors accomplish nearly two and one-half times the amount of work done with horses in the same time. In other operations such as harrowing, disking, weeding, and drilling tractor farmers do from two to three times as much work as those who use horses. On some farms where horses alone are used for motive power the difference is not so great because of the use of large teams and machines. No doubt big teams, used with proper eveners and hitches, should have a larger place than they now occupy on many of the horse-operated farms.

The operations for which the tractor was most generally used (plowing, disking before plowing, and harvesting with the combine) are operations which replace a large number of horses and at the same time save man labor.

### Equal to 22 Horses for Plowing

In plowing, the tractor farmer of eastern Oregon accomplishes an amount of work equivalent to the work of 22 horses for the same period of time; in disking before plowing, the equivalent of 33 horses; and in harvesting and threshing with the combine, the work of 25 horses.

The use of tractors in this area results in a saving of man labor in the performance of these various operations which varies from 0.3 to 0.6 man hour per acre.

Expressed in terms of total man labor saved for an entire year and horses displaced through the purchase of a tractor, this study showed that on tractor farms there was an average of six less head of work stock than on nontractor farms that were approximately the same size as the tractor farms. It is believed that further reductions in the number of horses could profitably be made on many farms after the purchase of a tractor. The total man labor for the year was 0.8 month less on tractor than on nontractor farms. While this saving is small the real advantage of the tractor is in having a large unit of power available when needed, thereby allowing the work to be done in season.

### Competent Tractor Operator

Of the disadvantages of tractor operation, lack of skill on the part of the tractor operator is of major importance. The skill required to operate a tractor successfully is probably greater than for most other kinds of farm machinery. Unless the tractor owner is mechanically inclined and operates the tractor himself or is able to hire a thoroughly competent tractor man, he is almost certain to find his tractor an unprofitable investment.

Cost of operation is only one of the factors that should be taken into consideration in deciding whether the tractor should be substituted for horses. Costs of using tractors and horses vary as changes occur in the price of work stock, feed, tractors, fuel, oil, etc.; and while the cost of motive power was somewhat higher on tractor than on nontractor farms during the period 1920-1922, prices of horses and feed were relatively low during these years. Many farmers, particularly those on the larger farms where large acreages are tended in a comparatively short time, prefer the tractor to horses. In recent years improvements have been made in the type of tractor generally used in eastern Oregon. The machines are lighter and consume less fuel in doing a given piece of work. The bearings in some of the later makes are better protected from dust and probably cost less for repairs than some of the older makes.

Although the use of a tractor usually means a greater outlay of cash for operating expenses than the use of horses, tractors take much of the drudgery out of farm work and many farmers derive more satisfaction from their use than from the use of teams.

R. S. Washburn.

## TURPENTINE Lease Form Adapted to Farmers' Needs

In these days of comparatively good prices for turpentine and rosin, southern farmers are constantly receiving offers for turpentining privileges on their land. Many men, seeing their neighbors' timber wrecked by too early working of small trees, too deep chipping, too much wood being taken off each week, and by the working of more faces than the trees would stand, are reluctant to allow their own timber to be chipped. Yet experiments at Starke, Fla., on the Florida National Forest near Pensacola, and at other points, have shown that timber does not suffer severe loss, either by death or stunting, under conservative turpentining. The loss in the experimental trials at Starke, in second-growth slash pine over a four-year operation, has been at the rate of one-half of 1 per cent of the trees annually. In young long-leaf pine in four years the loss has averaged a little over one-half of 1 per cent annually.

Conservative work can be assured the timber owner only by a written agreement with the operator in which certain restrictions are placed upon the work and good practice is required throughout. Leasing timber by the block or "lot" with no diameter limit set, below which trees must not be chipped, is apt to result in close cupping and consequent timber damage. The only safe way is to lease by the crop, designating specifically the trees which are not to be chipped. A main point on which further information is needed is the size of the smallest tree which the owner should allow to be chipped. But in the light of the best information available at present it is considered that a 9-inch limit is advantageous to both the timber owner and the operator.

The following form of contract contains the essential provisions for safeguarding the timber owner's interests. These provisions are particularly adapted to young stands of timber. The rental charges per face and other financial provisions vary from year to year, and the figures used in the following lease (in italics) are for purposes of illustration only, roughly representing conditions as they prevailed in 1925. In drawing up a contract the italicized words and figures in this lease would be omitted and the blanks thus made would be filled with appropriate words and figures.

### NAVAL STORES AGREEMENT

*I, John Doe*, of *Good Pine*, State of *Florida*, hereby agree to work for naval stores certain timber on the lands owned by *Richard Roe*, *Tall Timber*, *Fla.* Said timber is all the long leaf and slash pine timber not excepted under the terms of this agreement located on an area of about *40* acres to be definitely designated by *Richard Roe* before cupping begins in *section 9 township 4 North, range 6 East, Tallahassee meridian and base line*, upon which it is estimated that *2,000* cups, more or less, may be placed. In consideration of the granting of this privilege to *me* for a term of three years *I* do hereby promise to pay *Richard Roe* the sum of *$300*, more or less, as may be determined by actual count at the rate of *$150* per thousand cups, payable on or before *March 15, 1926*.

And *I* further promise and agree to work said timber in strict accordance with the following conditions:

1. No tree will be cupped, chipped, raked, or worked in any manner until payment has been made in accordance with the terms of this agreement.

2. Title to the product of the timber included in this agreement will remain in *Richard Roe* until it has been paid for as herein prescribed and removed from the tree.

3. No timber will be cupped except that on the area designated by *Richard Roe;* and all timber on that area will be cupped except as herein specified.

4. No marked tree and no tree 9 inches or less in diameter at a point 2 feet above the ground will be cupped; not more than one cup will be placed on trees from 9 inches to 14 inches, inclusive, in diameter; not more than two cups will be placed on trees from 14 inches to 22 inches, inclusive, in diameter; and not more than three cups will be placed on any tree.

5. The greatest depth of streaks will not exceed one-half inch, excluding the bark. The width of the streaks will be so regulated that not more than one-half inch of new wood will be taken off at each chipping. The faces chipped or pulled the first season will not exceed 15 inches in height from the shoulder of the first streak of the season to the shoulder of the last streak of the season, including both. The faces chipped or pulled in subsequent seasons will not exceed 15 inches in height, measured in the same way. A No. 1 or smaller hack or puller will be used for chipping or pulling. Bars or strips of bark not less than 4 inches wide in the narrowest place will be left between faces, and this width shall not be lessened as the faces progress up the tree. Where more than one face is placed on a tree, one bar between them will not exceed 8 inches in width. The first streak at the base of the face will be made at the time the apron or gutter is placed. Not more than one streak will be placed on any face during any week. Faces not chipped in accordance with these specifications may be marked out and the cups removed by *Richard Roe*.

6. A cupping system satisfactory to *Richard Roe* will be used, and the cups and aprons or gutters will be so placed that the shoulders of the first streak will be not more than 6 inches distant from the top of the cup, and the cups first placed will be as near the ground as possible. No wood will be exposed on any tree by removing the bark below the gutter or aprons.

7. No unnecessary damage will be done to cupped trees, marked trees, or to trees below the diameter limit. Trees that are badly damaged during the life of this agreement, when such damage is due to carelessness or negligence, shall be paid for at the rate of *$6* per thousand feet board measure, full scale. Trees split or wind thrown because of deep incisions for raised tins will be considered as being damaged unnecessarily.

8. No cups will be placed later than May 15, *1926*, without written permission from *Richard Roe*, and all timber embraced in this agreement will be cupped before said date. The cupping will proceed with all reasonable speed.

9. Unless extension of time is granted, all timber will be chipped, dipped, and scraped, the product and all cups, aprons, gutters, and nails removed, and each cupped tree thoroughly raked to the satisfaction of *Richard Roe* not later than December 31, 1928. Tins will be pulled out, not chopped out.

10. No fires will be set to the timber, underbrush, or grass on the area covered by this agreement without the written permission of *Richard Roe*, and during the time that this agreement remains in force *I* will, independently, do all in my power to prevent and suppress unauthorized forest fires on the said area and in its vicinity, and will require my employees and contractors to do likewise.

11. All cupped trees will be raked in a workmanlike manner for the space of 2½ feet around each tree during December of each year of the life of this agreement; and, if required by *Richard Roe* a fire line not less than 3 feet wide in the narrowest place shall be hoed or plowed around the area covered by this agreement in such a manner as to completely isolate it from adjoining lands. Natural fire breaks, such as creeks, swamps, roads, etc., may be utilized with the consent of *Richard Roe*. These fire lines must be made

and receive the approval of *Richard Roe* before any cups are placed the first year or new streaks made at the beginning of each subsequent year.

12. *Richard Roe* reserves the right to sell or otherwise dispose of and remove or have removed all dead timber and uncupped living timber from the area covered by, and during the life of, this agreement: Provided, That the removal of such material will not interfere with the operations of the purchaser.

This agreement will not be assigned in whole or in part without the written approval of *Richard Roe.*

The conditions of the sale are completely set forth in this agreement, and none of its terms can be varied or modified except in writing with the approval of both parties.

And as a further guarantee of a faithful performance of the conditions of this agreement, *I* deliver herewith a bond in the sum of *$500*, and do further agree that all moneys paid under this agreement will, upon failure on *my* part to fulfill all and singular the conditions and requirements herein set forth, or made a part hereof, be retained by *Richard Roe* to be applied as far as may be to the satisfaction of *my* obligations assumed hereunder.

Signed in duplicate this *twentieth* day of *December, 1925.* Witnesses (corporate seal, if corporation).

LENTHALL WYMAN.

## TURPENTINE Pine Chipping to Get Highest Yields

Keen competition makes it necessary for the successful turpentine operator to keep down his costs, get the highest possible yield from his long-leaf pine and slash-pine timber, and maintain the vigor of his trees by proper working. Also the approaching shortage of suitable turpentine timber, with the consequent heavier charge for leases, is a powerful argument for avoiding all possible waste.

The first and most obvious step is to eliminate poor-yielding trees or those likely to die or dry face shortly after the cups have been hung. In old-growth timber, stag-topped trees and trees with dead limbs and very thin sapwood are apt to dry face. In young stands, trees crowded on all sides and with poor tops, thin foliage, and no taper should be marked out. Leaning trees and those with very crooked stems should not be worked. Trees less than 9 inches in diameter, 2 feet above the ground, give such small yields that only in times of very high prices is there any money in working them.

These smaller trees lower the average yield of a crop of faces surprisingly. For example, on a tract under lease by the Southern Forest Experiment Station near Starke, Fla., there are 3,330 faces on trees over 7 inches in diameter. These faces yielded 11.6 barrels of spirits for the 1925 season, or at the rate of 34.8 barrels per crop of 10,000 faces. If trees below 9 inches had been excluded the yield would have been 43.5 barrels per crop. The small trees alone yielded at the rate of only 24 barrels per crop. On the basis of average prices for the five-year period 1921–1925, the returns from trees 9 inches and over were $3,156 per crop. Operating costs, including leasing, working, stilling, and overhead, were estimated to be $1,814. The net profit was $1,342. Operating the 7 and 8 inch trees cost $1,619 per crop, the returns were only $1,709, and the net profit but

$90. Had 1924 prices prevailed there would have been an actual loss of $76.

Experience indicates that two-face trees should be at least 14 inches in diameter, 2 feet above ground, and three-face trees at least 18 inches.

### Faces Should Be on the South

In general, faces should be on the south rather than the north side and below the heaviest branches. Faces placed above old "cat faces" or fire scars are apt to dry out and become nonproductive.

In facing trees no wood should be exposed below the point where the tins are inserted, because fires can not readily ignite faces with no exposed wood close to the ground. The tins should be no further from the ground than is actually necessary for placing the cup. The oblong cup is not so deep as other kinds and permits the tins to be placed lower. Tins should be inserted lightly, so as not to interfere with the circulation of the sap behind the face.

Faces should be so placed that at least 4 inches of uncut bark will always remain between them. Where only one face is put on a tree not more than a third of the bark should be cut away. Though wider faces may yield more for a year or two they do not keep up high yield, and are not best over a long period. Tests have resulted in exactly the same rate of yield from narrow faces and from faces twice as wide, by the middle of the fourth working season. Meanwhile other trees with two faces aggregating a total width three times as great as the narrow ones were actually yielding less than the narrow faces because of the large percentage of the trees unproductive or dead as a result of overwork.

### Sharp Tools Necessary

Sharp tools are essential. Dull ones are reputed to bruise the resin duct cells, causing gum to stop running sooner than it otherwise would, although no records bearing on this point have been kept. For best results the edge or shoulder of the face should be kept even and regular. The angle of the peak should not be very sharp since a long peak has a tendency to dry out. But a moderate slope to the streak makes a cleaner cut possible, with the same effect on yield as the use of sharp hacks and pullers.

A strong opinion prevails among operators that a first or "advance" streak should be made at the time the cups are hung, following which four to six weeks should elapse before the regular weekly chipping starts. Thenceforth regularity of work is insisted upon by the best operators.

The season of work depends, of course, upon the weather. If the best trees give only small yields in the cool weather at the beginning and end of the season, the little trees will fail to do even fairly well at such times. Therefore, the wise operator will, so far as possible, start chipping in his drifts of large trees, and will continue working them later in the fall than drifts of small timber. The small trees should be handled on a short season, when the weather is most favorable for heavy gum production.

In the light of present knowledge weekly chipping seems most satisfactory. Fortnightly streaks, at half the chipping cost, netted

70 per cent as much gum as weekly work in one of the Southern Forest Experiment Station tests. However, a rough comparison of costs showed less profit for the fortnightly chipping, since chipping costs, in which the largest saving was made, are only a small part of the total cost. Twice-a-week chipping of virgin long-leaf pine in Mississippi some few years ago proved unsatisfactory because so many trees died during the second year as to offset the large yield of the first year.

FIG. 248.—By chipping lightly and with a small-sized hack and by following good woods practice the life of a turpentining operation can be extended several years

Experience with various styles of chipping shows conclusively that it is unnecessary to take off more than half an inch of wood up the tree at each chipping; even less than this is recommended on the basis of experiments under way since 1923. When the width of streak was not over three-eighths of an inch the yield over a four-year period was greater than when it was three-quarters of an inch. The advantage of being able to work the face for a longer period is obvious.

The use of small hacks and pullers is increasing among successful operators, because this automatically limits the amount of wood cut away. With small tools a face can be worked for one or two years longer than with large tools. A No. 0 hack and a No. 1 puller are large enough except where the bark is extremely thick. An open-throated small hack is now on the market that does away with the objection, sometimes raised, that No. 0 hacks choke up badly. This modified hack has all the advantages of the regular No. 0 hack and plenty of room for chips and bark to fall through without choking.

### Vary Chipping Depth

The wise operator will vary the depth of chipping according to the character of the timber. Young long-leaf pine may stand chipping up to 1 inch deep without serious injury, but the yield is not what it should be during the third and fourth years. Young slash pine, if not too crowded, will stand three-quarters of an inch without much dry face, at least in wet seasons. Old thin sap trees require very light work, and crowded young slash is very susceptible to injury from deep chipping. All timber should be chipped lightly during periods of drought. One-half inch for slash pine and five-eighths for long-leaf pine are conservative depths, if faces are to be worked over a four or five year period.

In scraping it is advisable to avoid taking off wood with the scrape, as this has a tendency to dry face the less vigorous trees.

Deep cuts for inserting tins when cups are raised often result in dry facing. The use of saw-tooth aprons is suggested, since they will hold solidly even when the cut is very shallow.

LENTHALL WYMAN.

## UDDER of Dairy Cow: Its Structure and Capacity

The udder of the dairy cow is one of the most important manufacturing plants. The farm value of the milk produced in one year in the United States amounts to over $2,500,000,000, which is more than one-fourth the value of all the food products in this country. Information concerning the structure and the operation of manufacturing plants turning out such an immense value of product is desirable and likely to prove of important economic value.

The udder is one of the most important parts of the dairy cow, but its internal anatomy, its capacity, and its performance are none too well understood. In much of the literature on dairy type or conformation, comments on these points are for some reason omitted. References to the subject are not by any means in close agreement.

The udder consists of two separate, elongated, flattened mammary glands, placed side by side and separated and supported largely by a heavy layer of tissue. Each gland ordinarily has two teats, the walls of which are relatively thin. Each teat has a single duct of considerable diameter occupying a large proportion of its volume.

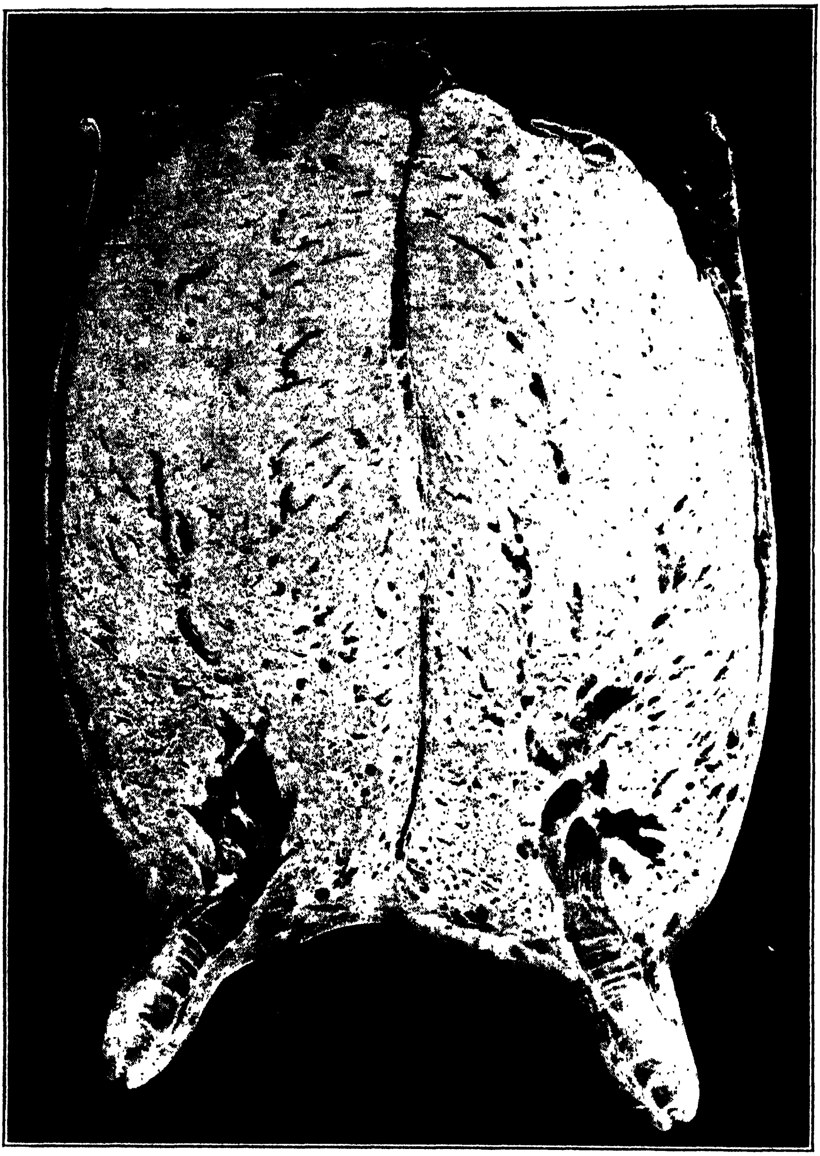

FIG. 249. -A vertical transverse section through the rear quarters of a hard, fleshy, fibrous udder. It took more than 3 gallons of fluid to fill the secretory system of this udder

The teat canal communicates freely above with a cavity of variable size and indefinite shape and outline, commonly known as the milk cistern, which is the terminus of a number of large ducts emptying into and forming a part of it. In some cases, strands or layers of heavy tissue are found passing through the cistern, dividing it into communicating chambers. The ducts branch profusely and diminish in size as they penetrate the apparently more dense mammary tissue. They serve not only to convey the milk from the secreting cells to the cistern and teat canal but also to store the product within the gland until it is removed either by the sucking of the young or by mechanical or hand milking. Figure 249 shows a vertical trans-

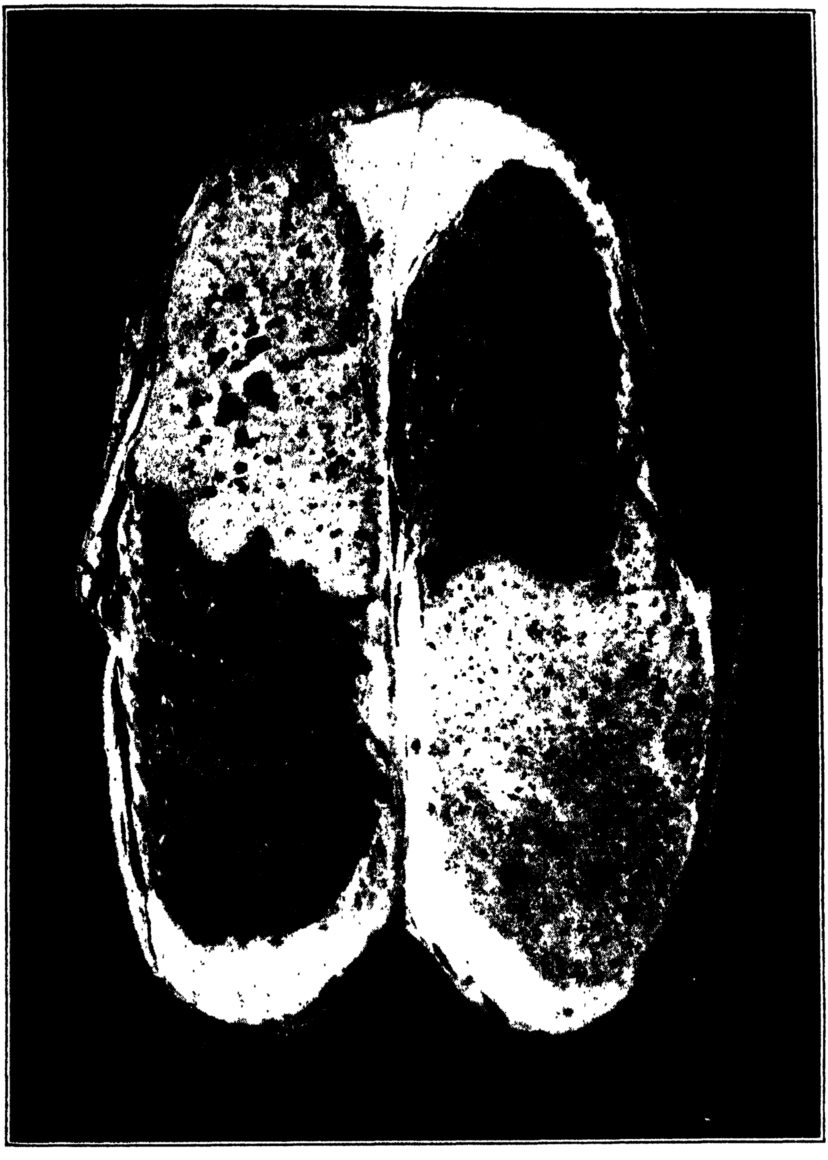

FIG. 250.—Horizontal transverse section of an udder (parallel to floor) showing that each of the four quarters is distinct

verse section through an udder and gives a general idea of its gross structure.

### Quarters Are Distinct

Although it is generally accepted that the right and left halves of the udder are distinct, it is more or less commonly believed that some communication exists between the front and rear quarters on the same side. A study of the manner in which the mammary glands develop in the heifer from birth to maturity gives evidence that the quarters are distinct. The first traces of glandular development can be detected very soon after birth in the form of a single tiny straight tube leading from near the abdominal attachment to each teat. This tube or duct can be felt by rolling the tissue between the thumb and finger. Each one is distinct, and they are widely separated. In developing, these tubes first become enlarged near the center and then elongate vertically. The front and rear ones on the same side continue to enlarge and approach each other until they join at the base, leaving a V-shaped depression above. Gradually this depression becomes filled with tissue, and they become continuous. Since the two quarters on the same side develop from entirely distinct units, it would hardly be expected that they would communicate even though they approach and finally become attached to each other.

To illustrate the distinctness of all four quarters, an udder was removed from a mature cow after the milk had been drawn in the usual manner. A clear formalin solution was pumped through the teats into the left front and right rear quarters, while the right front and left rear quarters were filled in a similar manner with a formalin solution carrying a red dye. The udder was then frozen and sawed into horizontal transverse sections. Figure 250 shows one of these sections. The color line between the quarters is distinct, showing that none of the fluid passed from one quarter to another. No distinct septum is found between the front and rear quarters such as is found between the right and left halves, yet communication does not normally exist between them.

Judgment of the value of an udder and its capacity to function is ordinarily based upon its external size and shape (fig. 251) and upon the quality of its tissue. An udder that is hard or meaty is supposed to be deficient in capacity and in number of secreting cells. A common belief is that the capacity of the cow's udder is normally small and that the greater part of the milk obtained at any regular milking is secreted during the few minutes required for milking. A casual examination of a cross section of an udder gives the impression that the ducts are small and that the gland is largely a mass of tissue with only a limited storage capacity. Udder capacity as herein discussed is understood to mean the storage space within its secretory system.

### Udder Capacity Large

Recent tests have shown the capacity of the udder to be much greater than is commonly supposed. In determining its capacity, the udder is removed from the cow immediately after she is killed.

Care is exercised that the tissue is not cut or injured. It is milked out completely and suspended from a frame in as nearly a normal position as possible. A formalin solution is pumped through the teats into each quarter until it is filled. The udder is then frozen and sectioned for a study of its gross and microscopic structure.

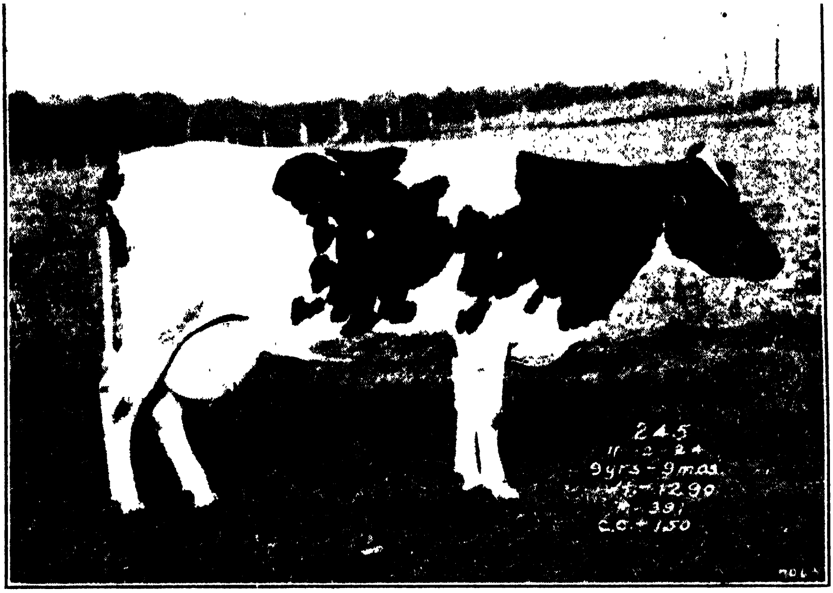

FIG. 251. - External side view of udder shown in Figure 249

Since the tissue is not cut in its removal from the cow the formalin is held within the secretory system. The quantity of formalin pumped into the udders is measured. The capacity of five udders has been determined in this manner and is shown in Table 30.

TABLE 30.—*Capacity*[1] *of the secretory system of the udder*

| Number of cow | Breed | Portion of udder filled | Amount of fluid used | Capacity of secretory system | Equivalent in milk |
|---|---|---|---|---|---|
| | | | *Cubic centimeters* | *Cubic centimeters* | *Pounds* |
| 245 | Holstein | 4 quarters | [2] 12,000 | [2] 12,000 | 27.26 |
| 221 | do | do | 13,000 | 13,000 | 29.53 |
| 243 | do | 2 right quarters | 4,700 | 9,400 | 21.36 |
| 459 | Jersey | do | 6,200 | 12,400 | 28.17 |
| 292 | Holstein | do | 10,200 | 20,400 | 46.35 |
| Average | | | | | 30.53 |

---

[1] For any who might be accustomed to think of udder capacity as the quantity of milk produced in two or more milkings during a period of 24 hours, it should be mentioned that capacities as given in this table refer to single fillings of the udder.

[2] Approximately.

No. 249 was a hard, fleshy, fibrous udder. It had been milking approximately six weeks, but had been infected. The quantity of formalin injected was approximately 12,000 cubic centimeters or between 3 and 3½ gallons. No. 221 was particularly coarse and fibrous. It had been infected and was secreting only a small quantity of milk. No. 243 had been dry for 12 months and was of the meaty type but shrunken in size. No. 459 was loose and yielding and had been lactating three months following a premature parturition. No. 292 was from a heifer in her first lactation period and had been lactating 43 days.

Since the staining solution which was injected into diagonally opposite quarters did not penetrate either of the other quarters, it is obvious that the four quarters of the udder are entirely distinct. Similarly, from the fact that the secretory systems of the five udders accommodated on the average a volume of formalin equivalent in milk to more than 30 pounds, it is evident that the storage capacity of a cow's udder is greatly in excess of that generally supposed.

W. W. SWETT.

## UREA—A Nitrogen Fertilizer with Many Advantages

Present fertilizer practices, as far as nitrogen materials are concerned, consist in using ammonium sulphate and sodium nitrate, containing, respectively, 25 and 20 per cent equivalent ammonia, either alone or in mixtures with other plant foods. The largest use of these two materials is in mixtures of rather low total plant-food content.

Several disadvantages are well recognized as attendant upon this practice. In the first place, freight charges, which are no longer an inconsiderable item in the farmer's fertilizer bill, are paid upon a large content of inert materials. Secondly, in the case of many of our present standard nitrogen carriers their use in large quantities adds to the soil an undesirable element.

Urea, which is formed by the reaction of ammonia and carbon dioxide, contains about 56 per cent ammonia. Its decomposition in the soil and utilization by the plants does not leave behind any undesirable materials. The carbon dioxide liberated after the ammonia has been used up is either absorbed by the plant or assists in the process of making phosphates available. Hence it is a highly desirable constituent in the soil.

### Synthetic Ammonia to Meet Requirement

The increased demand for fertilizer nitrogen will undoubtedly be met by synthetic ammonia made from coal, air, and water. During the manufacture of ammonia by this process, large quantities of carbon dioxide are formed as a by-product. In fact, more than enough carbon dioxide is produced by the water-gas synthetic ammonia process to combine with all the ammonia to form urea. Pure carbon dioxide, such as is obtained as a by-product from this process, has a real value and has many applications in other industries, for example, in the manufacture of dairy products, and in making the new refrigerant known as "dry ice." In the future, we may expect to see the fixed-nitrogen industry supply not only these more desirable fertilizers, but also a valuable product for churning and ice-cream manufacture.

The production of urea is a difficult chemical operation and all the problems in its production have not yet been solved, even in Germany where its production has reached substantial figures. It is confidently believed, however, that in the course of time the production of urea will be as easily accomplished as the manufacture of synthetic ammonia is to-day. The Department of Agriculture is endeavoring to solve these problems, to the end that the American farmers may have cheaper and better fertilizers.

H. J. KRASE.

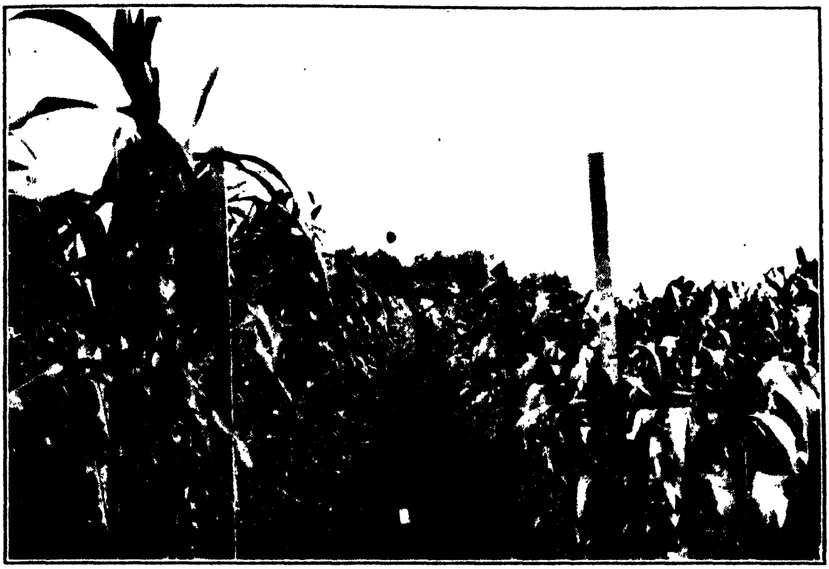

FIG. 252.—Growth of cotton with urea. At left, urea, 1,000 pounds 8–8–4 fertilizer per acre; yield, 1,412 pounds of seed cotton. At right, no nitrogen, 1,000 pounds 0–8–4 fertilizer per acre; yield, 736 pounds of seed cotton

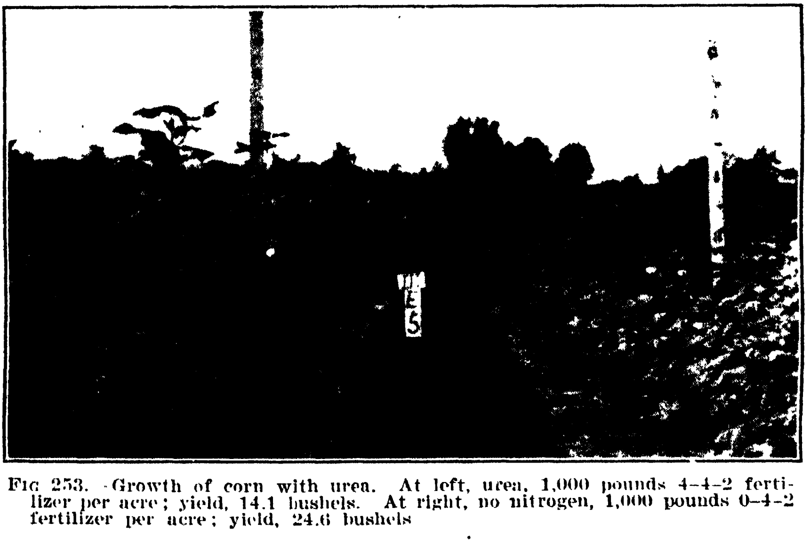

FIG 253.—Growth of corn with urea. At left, urea, 1,000 pounds 4–4–2 fertilizer per acre; yield, 14.1 bushels. At right, no nitrogen, 1,000 pounds 0–4–2 fertilizer per acre; yield, 24.6 bushels

**VEGETABLES and Their Varietal Stabilization** Stabilization is taken here to mean any process by which it may be possible to approach more nearly that ideal condition where all vegetable seed sold would be within a certain standard of purity as to varietal type.

The term standard is not applicable to the seed business in the same sense as, for example, to the manufacture of bolts, because the same uniformity and gradation is not possible. Turnips are not shaped by machinery, and soil and climate do not affect the making of bolts. The processes of stabilizing vegetable varieties and of standardizing manufactured articles therefore have little in common. In the case of bolts, the manufacturer and the dealer find that they have only a fraction of the number of types existing before standardization took place. This is the essence of the process of standardizing manufacture. But there is confusion as to whether the stabilization of turnip varieties shall mean fewer names in the catalogues or fewer shapes and sizes of turnips growing from any one packet of seed. There is demand for both sorts of simplification, but our definition includes only the latter. Many seedsmen would be glad to cut down the number of varieties, but the gardener is more interested in having what he buys as a certain variety of turnip always turn out to be 75 or 85 or 95 per cent the thing that he has in mind when he orders.

This sort of uniformity is also distinct from the rectification of varietal names, though there are points where the two impinge. It is not so important that the Georgia planter and the Michigan planter should both call a variety of turnip by the same name as it is that they should both get that variety when they order it. There is, of course, great need of authentication of the varietal names of vegetables, but that is not stabilization.

### Nature of the Problem

The possibility and the ease of the stabilization here considered are not the same with all vegetables. The ease of its accomplishment will depend on several things; first, the method of propagation. If vegetative propagation is used, the process of stabilization is easy and the percentage of purity attainable should be very high. This statement applies to potatoes, the Jerusalem artichoke, horseradish, and such other vegetables as are not propagated by seed. The stabilization of crops produced from seed, however, is very much more difficult. The work in this case is perennial and must be kept trued up continually each year. But among seed-propagated crops there is also much variation in the ease with which the varieties are kept pure. This will depend on whether the blossoms are habitually self-pollinated or cross-pollinated. Among the vegetables which are somewhat readily held true to type are peas, beans, tomatoes, and lettuce. There is some natural crossing in these plants, but it is usually slight. On the other hand, the habitually cross-pollinated plants, such as beets, sweet corn, cabbage, spinach, melons, watermelons, squashes, radishes, carrots, parsnips, and others, are very difficult to get to a pure type or to keep to that type when it is once obtained.

To all this must be added the question of warehouse mixture. Threshing machinery and warehouse handling require the closest care to prevent mixture. Peas, so far as crossing is concerned, are the safest of vegetables, but this fact is offset by the very great danger of mechanical mixing in putting the large quantities of seed through the threshing and cleaning processes.

It may be possible to weigh all these considerations justly and to express them properly in the percentage of purity required for each vegetable, but the problem will be very difficult.

### Accurate Descriptions Required

As a preliminary to setting a standard it will be necessary, of course, to have accurate descriptions made of each variety to be stabilized. To return to the bolts, this preliminary step will correspond to the specifications for manufacture. It will therefore be necessary for everybody to agree on what each name shall represent. The description can hardly be too accurate, too inclusive, or the illustrative materials (such as tracings, drawings, paintings, models, and herbarium specimens) too numerous, if the work is to be rightly or usefully done. It would seem also that since the greatest demand for this sort of stabilization is from persons who make their living at growing vegetables—truckers, canners, market gardeners, and greenhouse growers—the limited number of varieties grown by them, or, better yet, a selected partial list of these varieties, should be first tried.

It is worth while to consider the causes of the condition which has led to the demand for stabilization. The present-day seed business is very complex and the sources from which any one variety of turnip can be bought are very numerous. Is the seed trade more lax than formerly, or is the demand for uniformity a new thing? Certainly the seed trade can not be accused of having neglected its business. Certainly also this demand for uniformity has become vocal and insistent only in the last three or four decades, arising with our large vegetable growing and shipping industries involving market gardener, trucker, greenhouse grower, and canner. So the thing that is new is not the lack of stabilization, which is less than at any time in the past, but the need for stabilization, which has grown more urgent with recent years. This need may be met by organization and by the pooling of buying operations in some of the minor trucking and greenhouse varieties of vegetables.

Seed of Grand Rapids lettuce, for instance, can always be bought of satisfactory purity in sufficient quantities to supply everybody. Probably also poor stocks are sometimes obtained by the careless buyer. The case is very different in that variety in which the most money is invested, and which is probably the single most important type handled by seedsmen, the Alaska pea. The seedsmen's hazard and investment are both very much greater here than with the lettuce, and there are occasional years of poor crops when there does not appear to be enough of the right sort of Alaska peas to supply the demand. Also, unfortunately, there are always considerable supplies of the wrong kinds of Alaska peas to be found, since these have legitimate uses for stock feed, forage, and the production of split peas.

To summarize, there has arisen in recent decades a demand for a degree of uniformity hitherto unknown in certain varieties of vegetables used for trucking, market gardening, canning, and greenhouse growing.

The better seedsmen have fairly well kept abreast of this demand. The consumers can not always be sufficiently informed to buy where buying is safest.

The task of fixing more definitely the types of commercial as distinguished from home varieties must be based on a full understanding of what each variety is, which means that exact varietal knowledge must precede any attempt at stabilization.

D. N. Shoemaker.

## VEGETABLE Mart Conditions in Rapid Change

The tendencies in marketing which are apparent to-day, even those which have been noticeable for several years may not prove to be permanent. The evolution of our fruit and vegetable industries has been so rapid that no one may predict with complete confidence just what will happen next. Much of our production still results from the exploitation of new regions. We can not tell whether the present methods of marketing are permanent until we know what areas are to be permanent sources of supply and upon what scale they can produce after the period of exploitation has passed.

### Visitation of Mildew

From about 1910 to 1925 it was believed that the Imperial Valley of California was the great permanent muskmelon patch of the United States and that its annual contribution would be limited only by the capacity of the country to consume the "cantaloupe" of commerce. In 1926 came a sudden and devastating visitation of mildew which lowered the quality and injured the reputation of the fruit. Shipments were sharply reduced. The whole industry is jeopardized. A marked tendency away from delivered sales and in favor of selling f. o. b. had been apparent in recent seasons but to-day no one knows whether buyers will continue to buy f. o. b. products of such doubtful quality.

Granting that there can be no long-time survey of trends in so new and variable an industry as is our long-distance marketing of vegetables, certain developments seem significant. There are certain hardy green vegetables such as spinach, cabbage, lettuce, celery, and several root crops, which are not seriously injured by ordinary frosts during most of their growing period. Furthermore, these products are not ruined if exposed to temperatures slightly below freezing while in transit or during distribution. They are therefore relatively safe crops for all who grow and handle them. Successive plantings can be made during the long, mild fall and winter season of the extreme South and Southwest and an occasional loss from an unusual freeze results in higher prices for the plantings immediately following which find a relatively bare market.

### Production of Safer Crops Stimulated

Marketing agencies are therefore promoting the growing of these products on a larger and larger scale. The areas of potential production are so large that there is a generally well-sustained pressure of supply on the market. More and more these products are finding their way into chain grocery stores and are kept constantly before the housewife in fresh and abundant supply and of fairly well-standardized quality.

The demand of the chain store for uniformity of grade is reflected all the way back to the grower. The trend toward standardization of quality and fairly uniform grading of our hardier green vegetables is evident and apparently permanent. Incidentally the retailer is doing all the advertising of these products. No growers' organization is doing any extensive consumer advertising of green vegetables.

Ever since extensive vegetable production at great distances from market was first undertaken there has been a tendency on the part of the grower to decline to take all the risks. He has required the stimulus of an advance of money to persuade him to plunge heavily in so hazardous a venture. The truck crop is not a banker's security. The dealer desiring large and continuous supplies has had to provide a large part of the cash to produce the crop. There seems to have been a steady trend toward tying up large-scale truck production more and more closely with marketing agencies willing to finance the grower. Thus the first wholesale handlers of these products have, in the aggregate, acquired steadily increased financial interests in the production of the crops they sell.

The cooperative movement has, on the other hand, made but little progress among growers of highly perishable, short-season truck crops for distant shipment. Memberships are too transient; production too variable; market prices too fluctuating; management too intricate; and season of operation often too short to make probable a large measure of success.

### Long-Distance Competition

A third trend is definitely discernible. The long-distance shipper of standardized products tends to compete more and more persistently with the local grower during the season for homegrown products. This results from the two trends first mentioned. Local truck crops have heretofore been sold largely ungraded or with little uniformity of grading. They are therefore not suitable for chain-store distribution, nor for other outlets which the larger dealers have developed for their graded goods from distant sources. Thus the local grower is finding much of the cash business of his home market closed to him. Many thrifty cash buyers who once went to a farmer's market now buy many fresh vegetables of entirely satisfactory quality at a chain store.

This situation has developed a fourth trend, the door-to-door sale of fresh vegetables and fruits from motor vehicles, especially in relatively small towns, so that it is the village which is becoming the local gardener's outlet for much which the city once consumed. He sells to a peddler who, with his motor truck, can cover a wide territory and serve many consumers who can not conveniently patronize the chain store nor visit a public market. In this way many local growers may escape direct competition with graded products from a distance, but the chain store invades smaller and smaller communities and the day when the local gardener must grade his products very much as does his distant competitor seems close at hand.

### Products for Gardeners Near Cities

It seems inevitable also that commercial gardeners near large cities must specialize more and more on those products which, in their season, are better than any which can come from a distance and on those which are most difficult to transport without serious loss in quality. Among these are such crops as sweet corn, garden peas, and fresh-shelled beans of all kinds.

In spite of considerable discussion and some legislation in its favor the farmer's retail market does not appear to be growing in importance. Where these markets are well patronized they furnish an outlet for many fresh, ungraded products which can not be shipped profitably for long distances. Itinerant motor-truck operators also can dispose of much ungraded produce, for the purchaser is not prejudiced by a comparison of qualities. Aside from these outlets, however, the local producer will find careful grading increasingly necessary.

WELLS A. SHERMAN.

## VILLAGE Planning Contributing to Better Farm Life

Most American villages are social and trade centers for the surrounding farming community. Villages, as a rule, come into existence mainly to serve farmers. This may not be the purpose of those who start villages, but unless service to farmers is given, success is seldom attained. Villages are essential to farmers as places to trade, to market products, to procure the usual professional services, to worship, to educate children, and to satisfy social and recreational desires. A good kind of village is needed for "a good kind of life on the farm." Farmers, in their own interest, should protect and sustain the villages that serve them. Our best villages are those where the village and the farming people recognize and utilize their mutual relationship.

It is of interest to farmers that villages should be distinctive, wholesome, convenient, and efficient. In the march of industrialization and urbanization some villages are passing out of existence. Villages of a cohesive type, whose people are bound together by strong social and community life and civic pride, have the best chance to endure. Village people themselves should be interested in making their villages distinctive and serviceable, both for present use and for future expansion. Distinction and serviceability depend greatly on physical make-up. This necessitates good planning.

Some of the elements of good physical make-up of towns or villages are direct approaches, convenient and pleasing entrances and exits, broad tree-lined streets both direct and radiating, a common or village green, a civic center, open spaces, parks, and playgrounds, sanitary housing conditions, conveniently located and attractive public buildings, private dwellings and public buildings of good architecture set well back from the street and surrounded with ample lawns, and clean attractive borders. Such features make for civic efficiency, convenience, and social well-being.

In such places are found the farmer's automobiles on Saturday afternoon and evening. Here the ever increasing army of summer tourists make their stops. Such villages give promise of permanence, of becoming strong, virile, indispensable towns where the best citizenship is found, surrounded by a farming community that is satisfied with its marketing and recreational center.

### Planning Problems of Cities

Present-day cities are laboriously cutting out extraneous growths, removing excrescences, and rebuilding themselves to meet modern conditions. Great tenement sections are eliminated, costly buildings torn down, century-old trees uprooted, expensive suburban tracts acquired in order to create modern housing sections, widen thoroughfares, build civic centers, install gateways, and create public parks and playgrounds. Huge sums are spent annually to excise unhealthful situations which foresight might have prevented.

Must the 18,000 American villages look forward to these painful operations at maturity? Not necessarily! Some States are tardily leading the way in preventive planning for towns and villages as witness the work of the Massachusetts Federation of Planning Boards, the Iowa Town Planning Association, and the Wisconsin State Rural Planning Committee with its local county committees, all of which include villages in their ministrations.

The same may be said of such regional associations as the Niagara Frontier Planning Association, the Regional Planning Association of the San Francisco Bay Counties, and the Westchester County Planning Commission. State and private colonizing companies are building well-planned communities as at Ojibwa, Wis., Durham and Patterson, Calif., and in Pender County, N. C.

Notable new villages recently carefully planned with a view to esthetic and physical comfort are found at Mariemont, Ohio. Longview, Wash., Pinehurst, N. C., where certain farm lands were definitely set aside, and at Palo Verde, Calif., where exceptional provisions for parks and playgrounds were made.

Many foresighted villages are initiating their own planning practices. In some places this is accomplished by large-piece reconstruction work at one time, while in other villages the planning work is continued through many years. Weston and Cohassett, Mass., have replanned their town centers by removing old structures, broadening and straightening roadways, eliminating insanitary surroundings, and providing commons and establishing notable civic centers. (Figs. 254 and 255.) Brandon and Jericho, Vt., have grouped trade or public buildings about a public park or common with radiating tree-lined streets. Leroy, Ohio, and Waverly, Pa., have established civic centers. Forrest City, N. C., and Simsbury and Salisbury, Conn., have centered their planning activities on one main street. Newport, Vt., and Ashfield, Mass., have recently completed important planning developments about lake shores.

Other recent notable planning features are stream-side improvements at Logan, Utah, Cape Girardeau, Mo., and Lewisburg, Pa.; railroad gateways at Forrest City, Ark., Harper, Kans., and Post, Tex.; trolley gateways at West Milton, Ohio, Wheaton, Ill., and

Morrison Ridge, Kans.; park developments at Geary, Okla., and Waterloo, Wis.; playgrounds at Pipestone, Minn., and Elizabethville, Pa.; waterworks adornments at Norwich, N. Y., and Morrisville, Vt.; glen and waterfall reservations at Barre, Mass.; cemetery development at Bowman, Ga., Guttenberg, Iowa, and Geddes, S. Dak.; and vacant lot improvements at New Hampton, N. H., and Benwood, W. Va.

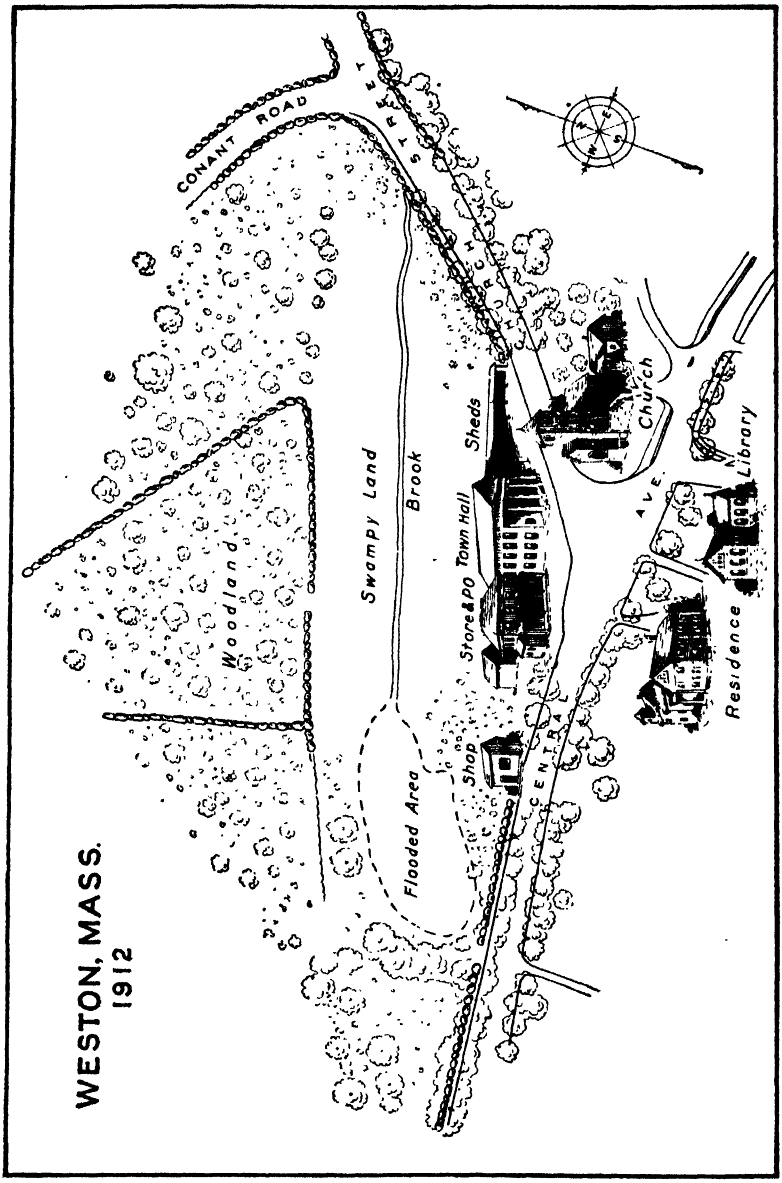

FIG. 254.—Weston, Mass., village center before replanning in 1912

A striking recent improvement is evident in the proper location, architecture, and ground improvements of public buildings such as schools, churches, libraries, town halls, courthouses, post offices, and community buildings.

The great sums now being spent for city planning are really for replanning and reconstruction, necessitated by earlier mistakes and haphazard growth. To plan a town is to exert careful control over its physical development as a whole. It is not a waste but a saving of money. It is made unnecessary to spend great sums in the future for reconstruction.

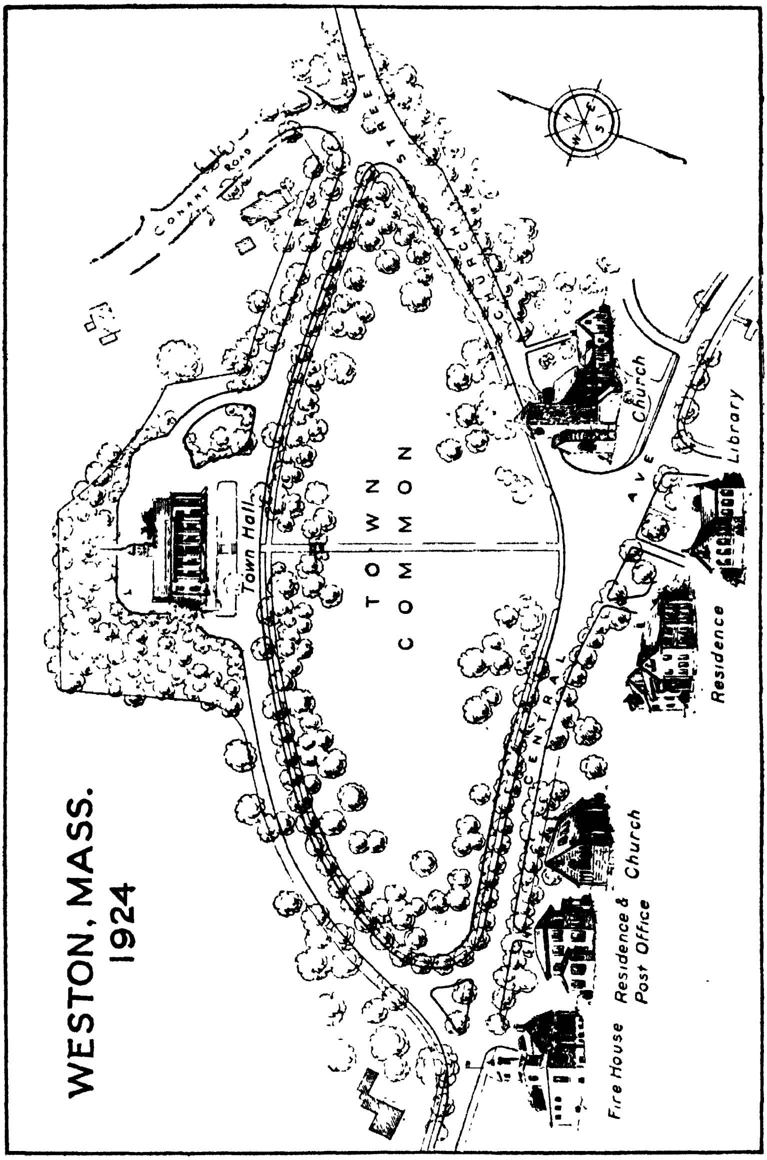

FIG. 255.—New plan of Weston, Mass., town common after replanning

Village planning is in its infancy in the United States. If rightfully carried out it promises much for the economic, social, and esthetic welfare of the 20,000,000 people who live in villages or small towns and the 30,000,000 farm people who use them.

WAYNE C. NASON.

**WAGES of Farm Labor in the Last 60 Years** The general trend of farm wages from 1866 to date has been upward along with prices, cost of living, and industrial wages. Farm wages were between 75 and 80 per cent of the 1910–1914 average in 1866 and 1869, dropping to less than 60 per cent, their lowest point for the past 60 years, between 1877 and 1880. From 1882 to 1893 farm wages continued at about 65 per cent, dropping to 61 per cent in 1894. Farm wages improved slowly during the remainder of the nineties, rose rapidly until 1905, and continued to rise at a less rapid rate until 1916 when, under the influence of World War conditions and postwar expansion, farm wages reached a peak in 1920 which was 230 per cent of the 1910–1914 average. Farm wages dropped to 150 per cent in 1921, and 146 per cent in 1922 during the more acute stages of the postwar deflation and depression period. They rose to about 160 to 170 per cent of the 1910–1914 average in 1923, at which level they have continued for the past several years. The general trend of farm wages from 1866 to 1925 is shown in Figure 256, together with the trends of industrial wages and of the general cost of living in cities and towns.

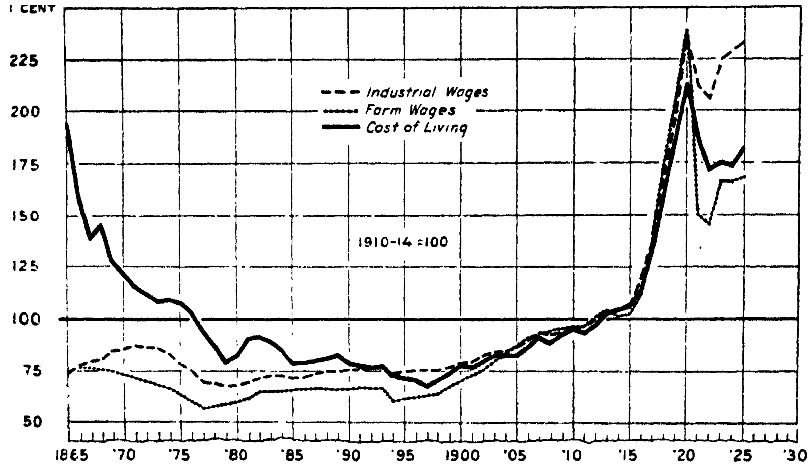

FIG. 256.—Farm wages, industrial wages, and cost of living, 1865 to 1925, inclusive

### Farm Wages and Industrial Wages

In 1866 both farm and industrial wages stood at 78 per cent of the 1910–1914 average, while the cost of living in cities and towns was more than double that amount, or 158 per cent. Neither industrial or farm wages reflected the high-price level of Civil War days. Industrial wages advanced to about 85 per cent of the 1910–1914 average during the first few years following the Civil War, while farm wages tended toward lower levels. Both industrial and farm wages reached the low point for the past 60 years during the late seventies. Industrial wages were not affected as much by the hard times of the nineties as were farm wages. Beginning with the late nineties farm wages began to rise more rapidly than industrial wages until about 1905 when they both continued to rise at about the same rate, reaching approximately the same peak in 1920. Both groups of wages dropped from 1920 to 1922, but farm wages dropped much farther. Farm wages during the past few years have been only about 160 to 170 per cent of the 1910–1914 average, while industrial wages have at no time been less than 200 per cent of the pre-war average and have since reached a point fully as high as the peak of 1920.

The cost of living decreased rapidly from 1865 to 1879 when it reached a low point at about the same time as both industrial and farm wages. The cost of living index was above both wage indexes until about 1890, but since 1890 it has been generally below industrial wages and except for a 10-year period from 1903 to 1913, above farm wages. The cost of living index started upward at the beginning of the World War, before wages, but did not reach as high a peak in 1920. It dropped from 1920 to 1922 and has remained slightly above farm wages, but very much below industrial wages.

### Factors in the Trend of Farm Wages

It is to be expected that farm wages and industrial wages would tend to have the same general trend over a long period of years. There have always been some shifts in labor supply from city to country and back again at certain seasons of the year and from year to year. If the wage inducements were great enough, the shift would be largely in one direction. High industrial wages at the present time are attracting farm laborers from the country. Since industrial labor has become better organized it has been able to keep wages moving upward in close harmony with the cost of living, with some slight lag, early in the war, and has even been able to hold industrial wages at the high war levels after the cost of living declined.

The recovery of business in 1922 and 1923 was reflected by a substantial recovery in both farm and industrial wages in 1923. The restriction of immigration was undoubtedly a contributing factor to this rise. But farm wages have remained between 160 and 170 per cent of the 1910–1914 average while industrial wages have reached a level fully as high as that reached in 1920. Although farm and industrial wages tend to have the same trend over a long period of time and are subject to many of the same influences such as deflation. business depression and recovery and immigration restriction, another highly important factor at work is the relative level of the prices of farm products as received by farmers.

Farm wages improved relatively faster than industrial wages from the late nineties to the beginning of the war in 1914. During that period the price of farm products increased relatively more than the prices of industrial products. It is undoubtedly true at the present time that farm wages are held at a lower level than industrial wages by the much lower level of farm prices. With farm prices of corn, cotton, and other farm products at present levels the farmer can not afford to hire much farm labor even at the present relatively low level of farm wages. On the other hand with industrial wages and earnings increasing, it is not likely that farm wages will decrease materially.

C. F. SARLE.

## WAGES of Farm Hands Governed by Three Factors

Farm wages appear to be influenced by three major factors: (1) Supply of farm labor, (2) cost of living, and (3) factory employment and wages.

The supply of farm laborers affects the wages they receive in very much the same way that the supply of a commodity influences its market price. An increased supply means lower wages or prices and a decreased supply means higher wages or prices. Since 1919, this relationship has been generally true if account is taken of the changes in the price level or cost of living.

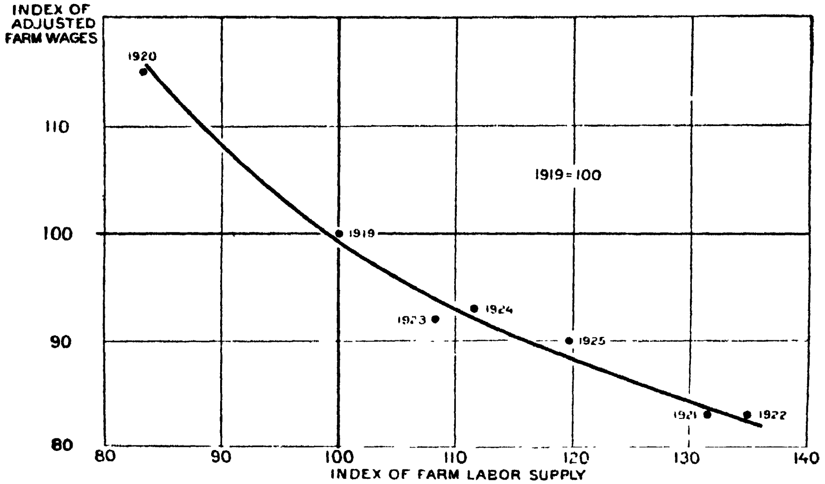

FIG. 257. Supply of farm labor and wages adjusted for changes in cost of living. An increase in the supply of farm laborers means lower wages, and a decrease means higher wages

In Figure 257 is shown a farm-labor supply and wages curve. The index of farm labor supply (measured horizontally on the figure) is derived from reports of farmer correspondents who indicate annually whether the supply and demand for farm labor in their localities are above or below normal. The index of wages is also based on reports by farmer correspondents. For use in this comparison, the reported average wages have been adjusted for changes in the cost of living in the United States and therefore represent changes in the purchasing power of farm wages. Both the supply and wage conditions of 1919 are here expressed as 100. Thus in 1921 the supply of farm labor in relation to the demand in that year was 31 per cent greater than in 1919. Wages, after allowing for the lower cost of living in the United States in 1921, consequently fell to 17 per cent from the 1919 level.

Factory employment and factory wages are both indirect factors in farm wages. During the past seven years for which data are available, increases in factory employment have been accompanied by decreases in the farm labor supply, and vice versa. Apparently when there is an active demand for labor in manufacturing industries, some farm hands are induced, probably by the prospect of higher city wages, to leave the farms, and when factory workers are laid off, some of them return to or seek employment on farms.

### Factory Wages an Influence

This movement of the labor supply between farm and factory tends to cause farm wages during the year to vary somewhat with factory wages except in the months of unusually heavy demand for farm hands. Thus since 1923 farm wages and earnings of factory workers have fluctuated in the same way in each season of the year except between April and July. The heavy demand for harvest labor during the past three years has caused farm wages to go up while factory wages declined. Evidently more hands were needed on the farm than were made available for farm work by the slowing down of manufacturing activity during the summer. Between October and January farm wages have declined more rapidly than industrial wage earnings, since the demand for farm labor in January is probably at the lowest point of the year.

## WASHING Clothes a Problem in Temperatures

Laundering has been done the world over ever since fabrics have been used for personal or household purposes. The aim has always been the same—to get out all the dirt and to get back the original color or whiteness without injury to the fabric. Many methods have been tried, in all countries, with varying degrees of success, from the primitive rubbing on the stones of the river bank to the modern washing machine.

The principle of all washing consists in sending a cleansing liquid through the clothes with sufficient force to dislodge the dirt. How hot shall this cleansing fluid be? This is an important question and when answered as the result of scientific study will go a long way toward working out a standard home-laundry method. For this reason the studies being undertaken at the present time by the department are emphasizing washing temperatures.

Before choosing the proper washing temperatures, a study must be made of the properties of soap, the characteristics of the common textile fibers from which fabrics are made, the kinds of soil that get on fabrics in everyday use, and the fastness of dyes to washing.

Friction and water are not enough to extract dirt from fabrics because loose dirt is held by a film of grease. Soap is needed also because it has the power of wetting greasy surfaces and of attracting to itself the dirt and grease, leaving the fabric clean. In order to act as a detergent, or cleanser, the soap must be dissolved in water. This is one of the reasons the temperature of wash water is important. Soap will dissolve at low or high temperatures depending on the kind of fat which was used in its manufacture. The vegetable fats usually produce soaps which can be dissolved in cool water and are so-called oleic acid or soft-oil soaps. Soaps made from animal fats, the so-called tallow soaps, generally require hot water to dissolve them. The temperature of wash water, however, does not depend alone on what will dissolve the different kinds of soap. Some of the textile fibers from which fabrics are woven are affected by water of different temperatures. Before buying the soap for laundering, therefore, it is important to know whether clothes can stand very hot water.

### Fibers Chiefly Used

The fibers which are used most extensively in the manufacture of textiles may be divided into three classes: (1), The animal fibers, including silk and wool; (2), the vegetable fibers, cotton and flax; and (3), the artificial fiber, rayon.

The animal fibers belong to a group of substances known as proteins and are soluble in an alkaline solution and injured by high temperatures. Wool is a slender, wavy fiber composed of elongated cells and covered throughout its varying length of three-quarters of an inch to 8 inches with minute overlapping scales. This peculiar structure of wool causes it to become felted when rubbed, or washed in very hot water or an alkaline solution. Silk, on the other hand, does not consist of a number of small cells, but is one long round filament. If unbroken in winding off the cocoon it may be as long as 40 feet. It does not shrink like wool, but is somewhat sensitive to heat and alkaline solutions. These properties of wool and silk suggest careful handling in laundering fabrics of these fibers, use of a neutral soft, oil soap, and need for lukewarm water for suds and rinses.

The cotton fiber comes from the fruit pod of the cotton plant and is three-quarters of an inch to 3 inches long. Under the microscope it looks like a twisted ribbon. Linen is made from the flax plant and the flax fibers are longer than cotton, varying from 12 to 36 inches in length. Flax fibers look like a straight ribbon with cross markings when examined with a magnifying glass. Both cotton and flax are made of cellulose and are not hurt by boiling water or weakly alkaline solutions. More drastic treatment can be used in washing fabrics of these fibers than is possible with silks and woolens. Brisk rubbing and stirring, a tallow laundry soap, and hot water can be used to good effect on cottons and linens.

Artificial silk, which is becoming more and more popular for undergarments and, in combination with other fibers, for dress fabrics, requires a certain care in laundering. It swells and loses strength when put into water and alkaline solutions. Therefore artificial silk fabrics must be squeezed rather than rubbed to remove the soil, and a neutral soap dissolved in lukewarm water used for suds and tepid water for rinses.

### Colors Cause Anxiety

A colored fabric made from any textile fiber always causes greater anxiety in washing than anything white. How it is going to come out is oftentimes a gamble. Recently, however, great steps forward have been made in dyes and dyeing, and colored fabrics have been produced which are more likely to launder well. Still it is universally known that colored goods must be separated from white goods in laundering and treated as gently as possible while getting them clean. The general rule is to use neutral soap suds no hotter than lukewarm, followed by rinses of the same temperature, and to wash and rinse as quickly as possible. The hotter the water, the more of the dye will be stripped from the fabric by the soap suds.

The kind of soil on clothing also has to be considered in deciding on the proper temperature for washing. Excluding stains, which have to be treated aside from the regular laundry process, there are four kinds of dirt: (1) Albuminous matter, as for example, eggs, blood, or any body excretion; (2) finely divided matter, as soot and dust; (3) animal and vegetable fats; (4) machine and mineral oils.

Albumin is the only one of these which is changed by a temperature between that of an ordinary room (70° F.) and of boiling water (212° F.). At a temperature about midway between these two, albumin changes to a form which will not dissolve in water, or becomes "set" on the fabric. The water for washing is generally somewhere between room temperature and boiling. If clothes have on them perspiration or other body excretions, or bits of food containing albumin, there is danger that these may be "set" or cooked into the fabric if the water is hotter than this halfway point. Very hot water may be needed, however, to remove other kinds of dirt. If this proves true, in the study now under way, then a preliminary soaking in lukewarm water will be recommended in order to get rid of the albuminous dirt.

In studying these various points on washing temperatures, pieces of different fabrics are being soiled and then washed in small cylinder washing machines with different degrees of hot and cold water. The cleanliness of the fabrics is determined by weighing and by the use of an instrument called a photometer. The results of all these studies will be translated into a standard method for home laundering which will take out some of the guesswork and make washing possible in the easiest, quickest, and most efficient way.

A. Elizabeth Hill.

## WHEAT Breeding for Resistance to Leaf Rust

All of the important varieties of wheat now grown in the United States are susceptible to one or more of the widely distributed forms of leaf rust. As a result leaf rust is usually prevalent on all of the wheat grown where humid conditions favorable for its development prevail. The amount of damage done by this rust varies considerably from season to season and from place to place. The crop seldom is ruined entirely but sometimes severe losses occur.

The hard red winter wheats, when grown in certain of the humid sections of the country, have been more or less resistant to leaf rust. The hard wheats, however, lack adaptation to humid conditions and can not be grown profitably. Over most of this area the soft red winter and white wheats give better yields than the hard red winters, although they are more susceptible to leaf rust. The possibility thus was presented of combining the resistance of one class with the adaptation of the other classes.

Experiments were begun in 1920, designed in part to study the inheritance of resistance to leaf rust but mainly to develop a wheat adapted to the humid winter wheat area and resistant to this rust. A series of hybrids were made between several strains of the Kanred variety, a hard red winter wheat, and soft red and white wheats. In later years Malakoff and other varieties have been used as resistant parents in numerous crosses.

In the course of these investigations hybrids have been made at Arlington Experiment Farm, Rosslyn, Va.; at La Fayette, Ind., in cooperation with the Indiana Experiment Station; and at Manhattan, Kans., in cooperation with the Kansas Experiment Station. Progenies from these hybrids have been grown at the places named and also at Knoxville, Tenn., and later in South Carolina and at several points in North Carolina, in cooperation with the experiment stations of the States named, and also in other States.

### Resistant Selections Tested

These investigations have now proceeded to the point where a number of selections that have shown resistance to leaf rust are being tested for adaptation and yield. In the early tests that have been made it is apparent that certain strains have been obtained that are resistant to leaf rust in the localities where they have been grown. Some of these have given good yields and thus appear to combine adaptation to these localities with rust resistance.

The breeding for resistance to leaf rust has been complicated by the fact that there are different physiologic forms of this rust which behave differently on different varieties. Twelve different physiologic forms, distinguishable by their reaction on different wheats, have been determined. With several of these forms present in any locality in proportions varying from season to season, as seems to be the case, the problem of breeding for rust resistance becomes very complex. The inheritance of resistance, as a consequence, can hardly be determined in field cultures. Despite these conditions the results obtained indicate that there is segregation for resistance and that the characteristic of low rust susceptibility has been transmitted to certain of the progeny in combination with certain other desirable characters.

### Resistance is Inherited

By studying in the greenhouse progenies of these hybrids between resistant and susceptible wheats, it has been determined that resistance is definitely inherited. In the greenhouse studies separate pure cultures of physiologic forms of leaf rust were used and the plants were protected from infection by other forms. Approximately three resistant to one susceptible segregates appeared in the $F_2$ generation of crosses where the hard red wheat Malakoff was used as the resistant parent.

In the $F_3$ generation the susceptible segregates bred true, while only one out of three of the resistant bred true, the other two segregating again into three resistant and one susceptible. In crosses where Malakoff was used as the susceptible parent, a segregation of one resistant to two intermediate and one susceptible occurred. These facts indicate that resistance in these cases is due to a single genetic factor.

In the case of crosses between two varieties, one which is susceptible to one form of leaf rust and resistant to another, and one which shows the reverse reaction to these two forms, the resistances of the two parents are independently inherited. A di-hybrid ratio in respect to reaction to these two physiologic forms of rust is obtained in the $F_2$. Resistance to the various physiologic forms so far tested is due, therefore, to different factors or groups of factors inherited as a unit, the different factors or groups of factors being independently inherited. These may be brought together, thus uniting in a single strain the resistance to the various physiologic forms possessed by the different varieties. It may thus be possible to develop a strain of wheat resistant to all physiologic forms of leaf rust. Experiments along this line are now under way.

C. E. Leighty.

## WHEATS Highly Resistant to Loose Smut

Loose smut of wheat causes an estimated loss of over 10,000,000 bushels annually in the United States. It is possible to control the disease by treating the seed with hot water, but the treatment is difficult to apply and frequently reduces the stand and the yield.

Since 1922 many varieties and strains of wheat have been tested at Rosslyn, Va., and Ithaca, N. Y., for resistance to loose smut. All of the important eastern wheats and a few of the leading western wheats have been included in the tests. As a result, resistant or immune strains have been found in the following varieties: Blackhull, Dawson, Fulcaster, Fultz, Hussar, Leap, Penquite, Preston, Purplestraw, Ridit, Shepherd, Silversheaf, and Trumbull.

The list includes some of the most important and widely grown varieties, such as Fultz and Fulcaster. Fultz, Fulcaster, and Dawson generally have been reported to be susceptible to loose smut, but the pure-line selections used in these experiments proved to be highly resistant. The occurrence of resistant and otherwise desirable strains in these widely grown wheats gives encouragement to the hope of reducing the heavy annual loss caused by loose smut of wheat.

V. F. Tapke.

## WHEAT Mosaic Control Through Immune Strains

The mosaic diseases of the winter cereals occur on wheat, rye, and barley and on wheat-rye hybrids. In the districts where wheat mosaic is prevalent it is very destructive to certain varieties.

The great economic and biological importance of the mosaic and other virus diseases of plants has stimulated many scientific workers to make extensive investigations of these diseases. Although the greatest interest seems to be centered around the attempt to discover the cause for these diseases, it should be emphasized that marked progress can be made in their control, even though it is not known what causes them.

The early studies on wheat mosaic indicated that the disease developed regularly from soil infestation. Further study showed that the virus can exist in heavy silt soils for at least seven years when winter wheat is grown every year or even at irregular intervals. This soil

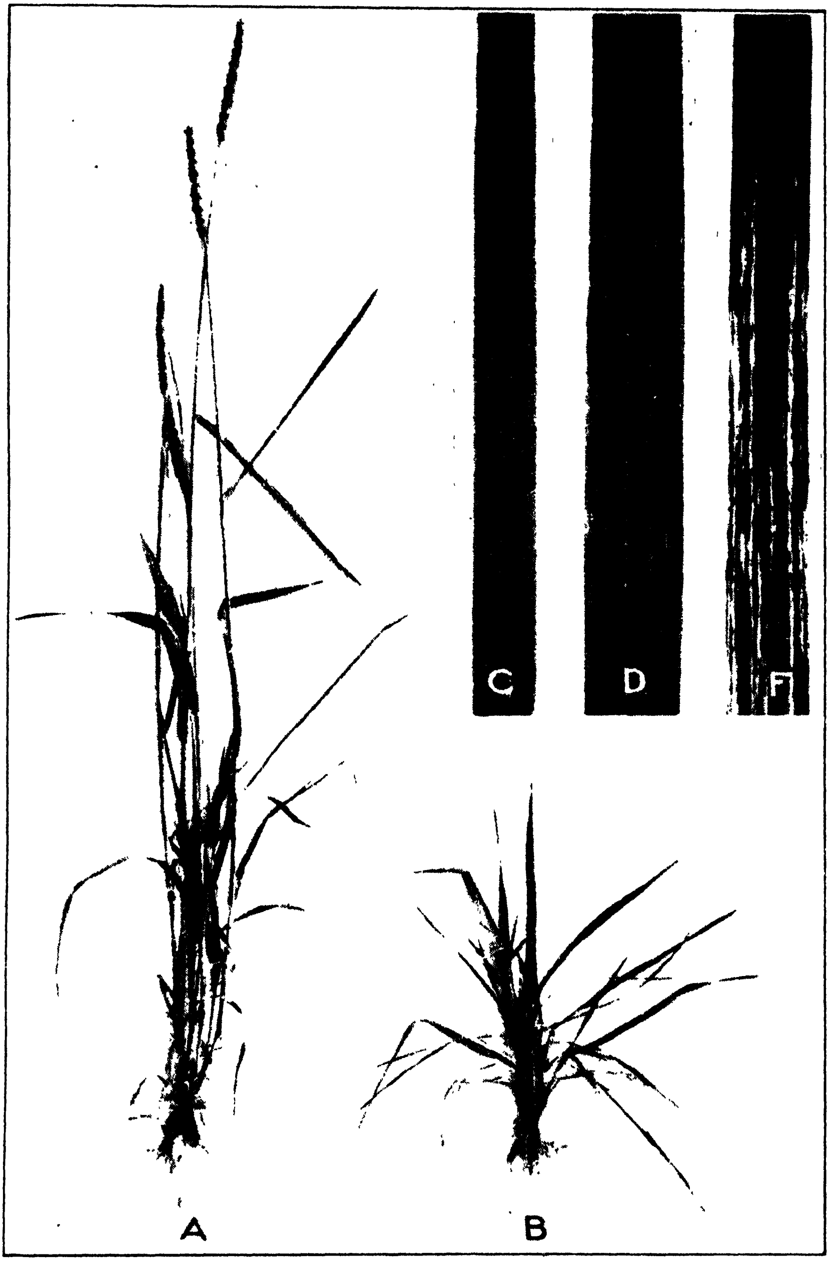

FIG. 258.—A, Healthy Harvest Queen plant; B, Harvest Queen plant showing a severe case of the rosette phase of mosaic; C, portion of a healthy leaf of wheat; D and F, portions of leaves showing mosaic mottling

relationship was so strikingly at variance with the accepted ideas relating to other mosaic diseases that wheat mosaic was thought for a time to be another type of disease.

The virus does not exist for as long a period in sandy soil as it does in the silt and clay types. This very likely is due, to a large extent, to differences in the leaching properties of the soils. It is evident, therefore, that soil type has an important bearing on its retention of a virus.

### Control of Wheat Mosaic

In the study of this disease it was fortunate that the far-reaching possibilities for controlling the mosaics through selection and breeding for resistance were made strikingly evident. This was brought about by a series of favorable circumstances, the most important of which were the existence of the virus in the soil and the extreme regularity with which the disease developed in wheat grown on uniformly infested areas.

Wheat is a very favorable plant for conducting disease-resistance studies. In no other crop have there been developed so many varieties and selections and in few others is it possible to study so many individuals on a small area of ground. This combination of favorable circumstances made it possible virtually to wipe out the losses due to wheat mosaic after a single season's study of varieties. Wheat mosaic is still with us, but it now occurs primarily on varieties which are highly tolerant to the disease.

Selection studies show that resistant or immune strains may be obtained from a very susceptible variety. Harvest Queen wheat can not be grown on soil containing a great quantity of virus, yet it has been possible to select individual Harvest Queen plants which are so resistant to mosaic that no appreciable losses occur, and in some cases it appears that there is complete immunity. The principal agronomic characters of these selections seem to be essentially like those of the original type, and it therefore appears that winter wheat mosaic can be held completely in check without sacrificing a valuable variety.

H. H. McKinney.

**WHEAT Reports on Production and Holdings** More complete and timely reports upon the domestic supply of wheat and its movement into consumption are now becoming available through a program put into operation by the Departments of Agriculture and Commerce. Under this program the Bureau of Agricultural Economics is collecting weekly reports of wheat in terminal markets, and quarterly reports of stocks on farms and in country mills and elevators, while the Bureau of the Census is collecting quarterly reports of wheat in merchant mills. These various reports have been adjusted to eliminate duplication, and taken together present a picture of the Nation's wheat supplies at three-month intervals.

Heretofore the Department of Agriculture published as of March 1 and July 1 estimates of wheat on farms and in country mills and elevators based upon questionnaires to crop reporters and elevator and mill operators. The reporters were asked to report on the percentage of the preceding year's crop which, in their judgment, was on hand on the given date. The new series of quarterly reports of stocks on farms will be based upon reports of actual production and actual holdings in bushels. Experience has demonstrated that such sample data give somewhat more accurate results. In like manner, operators of country mills and elevators are asked to report actual holdings on each date. From this sample the quantity held by all such establishments will be estimated.

### Data Heretofore Unofficial

Information on stocks in terminal markets has heretofore been gathered only by unofficial agencies. Two of the most commonly used reports of this character were those of the Chicago Board of Trade and Bradstreet's. The figure issued by the Chicago Board of Trade relates to 22 markets and does not include a number of markets, particularly in the Southwest, which have more recently become important, nor any markets in the Mountain or Pacific Coast States. The figure issued by Bradstreet's relates to over 50 markets, some of which appear to represent mill holdings, but does not include a number of markets which have recently become important.

The new series of reports on stocks at terminal points are designed to cover the holdings in about 42 markets in the following classifications:

1. In all public elevators.
2. In all private elevators or warehouses whose owners or operators are engaged in handling or storing grain in interstate commerce, except—
   (*a*) When the storage capacity of such elevator or warehouse is less than 25,000 bushels.
   (*b*) When stocks are for local merchandizing only.
   (*c*) When stocks are exclusively for local consumption by mills, crushers, or malt houses and are not expected to be offered again as grain in the markets.
3. All stocks afloat in boats or barges in lake, river, canal or seaboard ports of the United States which have not been cleared for export or shipment to another port.
4. Canadian grain in bond in these designated United States ports or markets.
5. United States grain in Canadian ports or markets.

### Mill Stocks Reports

Reports on stocks owned by merchant mills of 5,000-barrel capacity have been collected by the Bureau of Census beginning with June 30, 1925. Published reports show the stocks owned by mills which produced about 87 per cent of the flour production reported by merchant mills in 1923. Of the remaining merchant mills, many do not fall in the 5,000-barrel class, and are not carried on the current census lists. These smaller merchant mills are included in the Department of Agriculture country mill and elevator report. In order to eliminate duplication with Department of Agriculture reports the Census Bureau is now reporting stocks held at the mills separately from stocks owned but held elsewhere. This item of stocks held at mills supplements the Department of Agriculture items.

This joint arrangement of reports on wheat stocks does not include wheat in transit, either by rail or boat, nor in the small number of 5,000-barrel mills on the present census list which fail to report to that bureau. This last quantity, however, is small and an allowance can be made on the basis of holdings of those mills which do report.

The Department of Agriculture estimates of stocks on farms and in country mills and elevators on July 1 relate only to old wheat, while the reports of stocks in terminal markets and mills may include some new wheat.

JOSEPH A. BECKER.
H. S. IRWIN.

## WHEAT Varieties for the Western United States

Several new wheat varieties, introduced or developed through breeding by the United States Department of Agriculture in cooperation with State experiment stations, have been distributed in the Western States. Some of these already have achieved commercial importance and others may soon. The more important ones are described and discussed briefly under the commercial classes to which they belong.

### Hard Red Spring

The Kota variety was introduced from Russia and developed concurrently by the United States Department of Agriculture and the North Dakota Agricultural Experiment Station. It is a bearded, white-glumed variety which is resistant to black stem rust. It also is fairly resistant to drought and outyields Marquis in North Dakota and adjacent portions of neighboring States where it now occupies about 1,000,000 acres.

Reliance is a spring variety produced from a Marquis-Kanred cross in cooperative experiments between the Department of Agriculture and the Oregon, Montana, North Dakota, and Minnesota experiment stations. It is a bearded, white-glumed variety, maturing about one day later than Marquis. It is a vigorous, frost-resistant, and high-yielding variety. While it has the resistance of Kanred to stem rust it is not as resistant as Kota. Small samples of seed were first distributed for commercial growing from the Northern Great Plains Field Station, Mandan, N. Dak., in the spring of 1926. It should be best adapted to the western portions of the Dakotas and in Montana.

### Durum

Nodak is a pure-line selection from Kubanka developed at the Dickinson substation, Dickinson, N. Dak., in cooperative experiments between the United States Department of Agriculture and the North Dakota Experiment Station. It is similar to Kubanka except for being more resistant to stem rust and a higher yielder. Seed was first distributed for commercial growing from the Dickinson substation in 1923, and it is estimated that about 5,000 acres were grown in

1926. It appears best adapted to central North Dakota where stem rust is prevalent.

Mondak is a different selection from Kubanka but developed similarly. Mondak is not resistant to stem rust but yields best in Montana and in western North Dakota where stem rust does not occur. Mondak differs from Kubanka and Nodak only in being slightly later and taller, and having better quality of grain for the manufacture of macaroni. Seed was first distributed from the Dickinson substation in 1923 and from the Judith Basin substation, Moccasin, Mont., in 1926.

Akrona is a selection from Arnautka developed at the Akron Field Station, Akron, Colo., by the United States Department of Agriculture. It is an early, high-yielding amber durum and of excellent quality for the manufacture of macaroni. Seed was first distributed from the Akron Field Station, Akron, Colo., in 1925. It appears best adapted to northeastern Colorado and adjacent sections of neighboring States.

### Hard Red Winter

Karmont is a hardy, high-yielding selection of Kharkof developed at the Judith Basin substation in cooperative experiments between the United States Department of Agriculture and the Montana Agricultural Experiment Station. It is slightly hardier than Kharkof and yields best in the higher and drier sections of Montana. Seed was first distributed from the Moccasin substation in 1922, and it is estimated that about 350,000 acres were grown in 1926.

Newturk is an awnless hard red winter wheat developed from a Newton-Turkey cross in cooperative experiments between the United States Department of Agriculture and the Montana Agricultural Experiment Station at the Judith Basin substation. It is as hardy and as high yielding as Kharkof or Karmont in Montana, and of equal quality. Seed was first distributed for commercial growing in the fall of 1926.

Regal is a smut-resistant selection of Turkey developed in cooperative experiments between the United States Department of Agriculture and the Oregon Agricultural Experiment Station at the Sherman County branch station, Moro, Oreg. The Regal variety may be distinguished from other hard red winter wheats by its purple stems. Seed of the Regal was first distributed from the Moro Station in the fall of 1926.

### White

Federation was introduced into the United States in 1914 by the United States Department of Agriculture. It originated from a cross made by William Farrer, of New South Wales, Australia, and became the leading wheat variety of Australia. After being tested in the Pacific Coast States for several years, it was distributed to farmers in Oregon in the spring of 1920 from the Sherman County substation, and later in Idaho from the Aberdeen Field Station, Aberdeen, Idaho. About 450,000 acres of Federation were grown in 1925. It is an awnless, brown-glumed, soft-kerneled spring wheat, but is grown from fall seeding in mild climates. It is especially well adapted for growing under irrigation and on rich heavy soils.

Hard Federation was selected from Federation about 1908 by J. T. Pridham, at the Cowra Experiment Station, in New South Wales, Australia. It was introduced by the Department of Agriculture in 1915 and was first distributed in 1920 to farmers of Oregon and California from experiment stations at Moro, Oreg., and Chico, Calif. It is estimated that about 100,000 acres of Hard Federation were grown in 1925. It is a short, early, awnless, brown-glumed, hard white wheat, best adapted to the higher and drier sections of California, Oregon, and Montana.

Onas was introduced by the United States Department of Agriculture from Tulsa, Saddleworth, South Australia. It was developed through hybridization by F. Coleman, Federation being one parent. The value of this wheat for California conditions was determined in cooperative experiments by the department and the California Agricultural Experiment Station. Seed was distributed from the Davis Experiment Station, Davis, Calif., in 1923. It is a high-yielding, awnless, white-glumed, spring variety, best adapted to the low-lying good wheat lands of California.

### Value of the New Wheats

Of the new varieties listed above five already have proved extremely valuable to wheat-growing farmers. These are Kota, Federation, Hard Federation, Karmont, and Nodak. Their total estimated area in 1926 was 1,855,000 acres, and the total estimated increase in value from growing them was $5,525,000.

J. Allen Clark.

## WHEAT Varieties Resistant to Stinking Smut

For more than 2,000 years stinking smut or bunt has been one of the worst fungous parasites of the wheat plant. A hundred years ago the practice of treating the seed with blue vitriol was in general use in regions where outbreaks of the disease were common.

In the Pacific Coast States, owing to soil infection by wind-borne spores scattered during the harvest season, satisfactory control could not be obtained by seed treatment. Infection from this source was limited to winter wheat, for these wind-borne spores perish during the winter season and cease to be a menace to wheat sown in the spring. It was necessary, therefore, to try other means of control of stinking smut in winter wheat. The most hopeful solution of the problem seemed to be to find or develop resistant varieties. Accordingly, since 1913, when the nature of field infection was first demonstrated, thousands of varieties and hybrid selections have been tested for resistance at the experiment stations in Washington, Oregon, and California. The methods used have been similar at all stations. The seed is blackened with smut spores and sown at the time infection is most likely to occur. At harvest time the susceptibility is measured in terms of percentage of bunted heads.

Most of the common bread wheats have been found to be susceptible, producing from 25 to 100 per cent of bunted heads under such conditions. A very few varieties have proved to be highly resistant, producing less than 10 per cent of smut. In fact, three strains, White Odessa, Martin, and Hussar, have been smut-free in most tests at the various experiment stations, although they are susceptible to a specialized strain of stinking smut found in Germany.

Hundreds of hybrid selections that are smut-free in the third and later generations have been developed by the experiment stations during recent years. Evidently there are several factors, cumulative in effect, which contribute to the resistance of these wheats, for the hybrids are often more resistant than either parent. One such hybrid, from a cross between Turkey and Florence, has been distributed in Washington to more than 100 farmers, who find that it may be

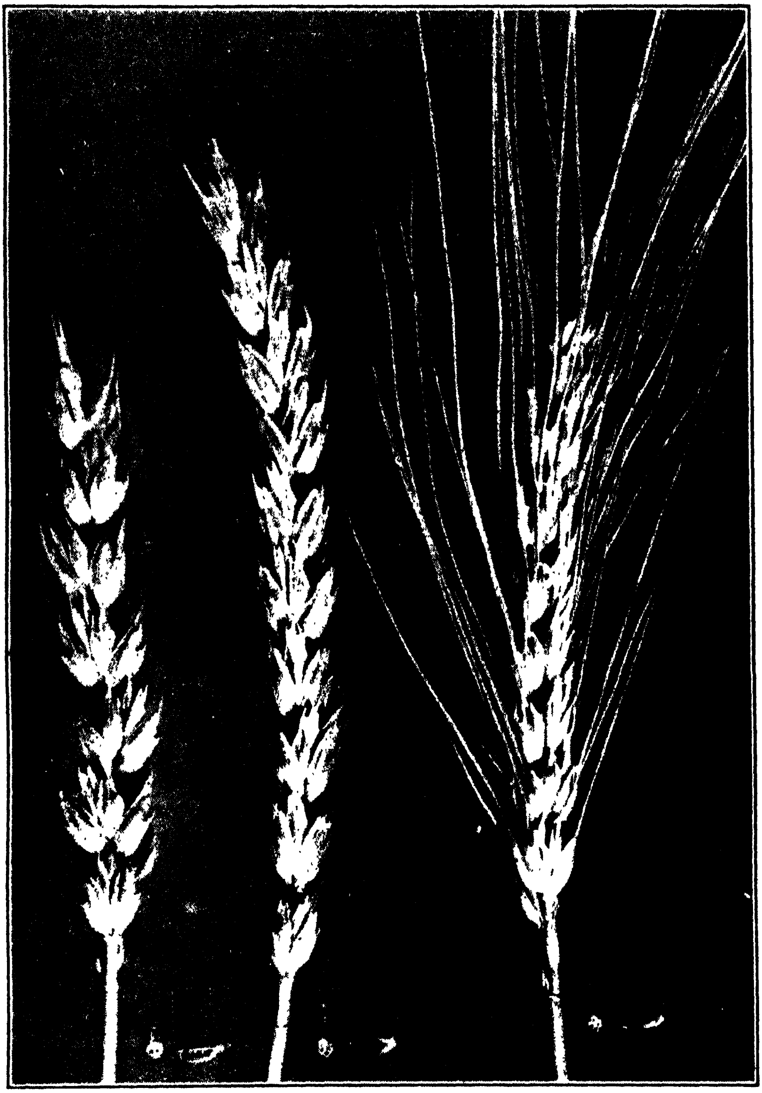

FIG. 239.—Ridit wheat and parents, Florence on the left and Turkey on the right. Ridit is a recent development of the Washington State Agricultural Experiment Station. It is more resistant to stinking smut than either parent, and may be sown without seed treatment without danger of a smutty crop

sown safely without seed treatment. Altogether, about 12,000 acres of Ridit (fig. 259), as the new wheat is called, were harvested in 1926,

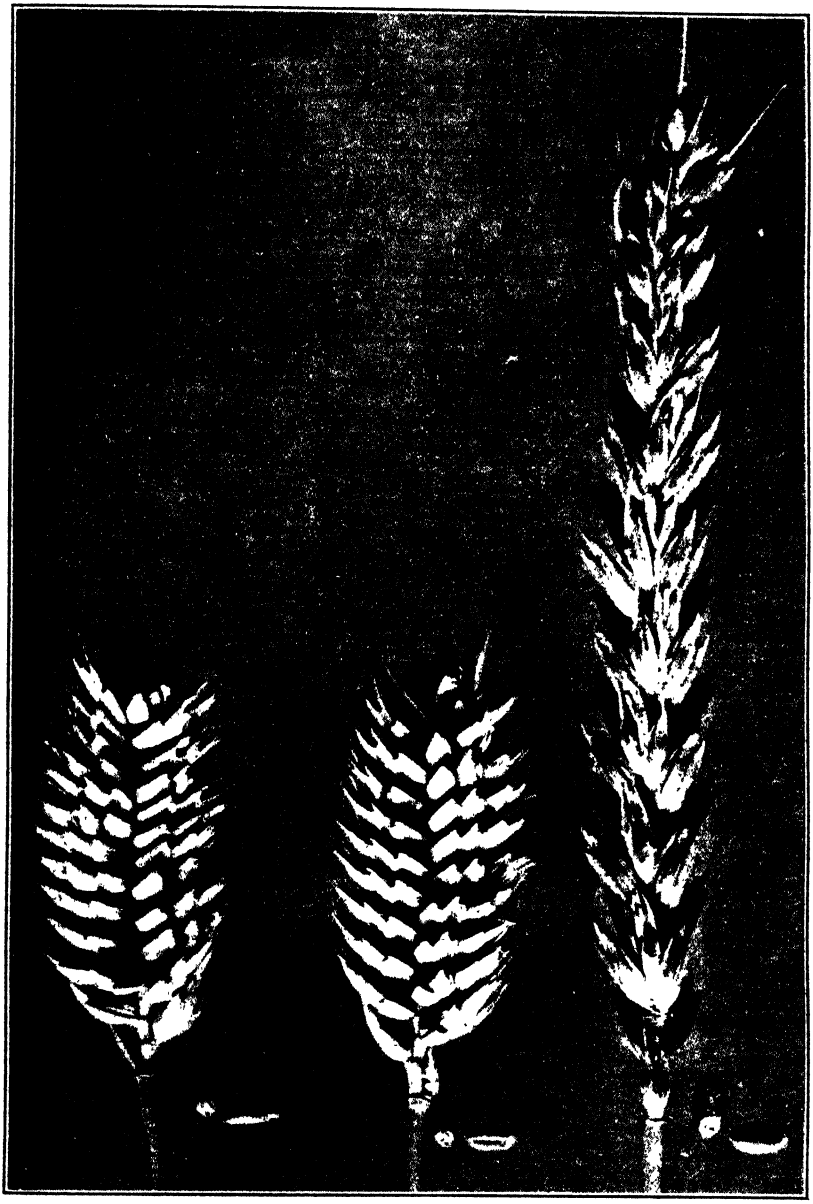

FIG. 260.—Albit wheat and parents, Hybrid 128 on the left and White Odessa on the right. Albit has the club head and stiff straw of Hybrid 128 combined with the immunity from stinking smut possessed by White Odessa

Another immune hybrid named Albit (fig. 260), resulting from a cross between White Odessa and Hybrid 128, has outyielded all the old commercial varieties during the past three years at the Washington station. In the seventh generation from the original cross it is being tested further by other stations of the Pacific coast, as well as by cooperating farmers in the winter-wheat sections of southeastern Washington and adjacent Idaho.

More than half of the wheat raised in the Pacific Coast States belongs to the white wheat class, and the remainder to the red groups. The introduction of Ridit, which is a hard red wheat, followed within three years by Albit, which belongs to the soft white type, is fortunate for a large increase of either class, by supplanting of the other, might entail serious marketing difficulties.

As the mode of inheritance of resistance to stinking smut has now been worked out and abundant immune material is available for breeding purposes, highly resistant varieties which will meet the climatic and market demands of the farmers should be available in a comparatively few years.

E. F. Gaines.

## WINTER Peas in the Atlantic and Gulf Plains

The Gray Winter field pea obtained from France by the United States Department of Agriculture in 1898 and the Austrian Winter field pea purchased from a New York importer of seeds in 1922 are very similar if not identical varieties judging from their behavior in the field. They belong to that group of peas which have colored flowers and dark-colored seeds, usually classified by botanists as *Pisum arvense.* The winter pea, as the name indicates, is able to endure lower temperatures than the ordinary varieties of field pea. In regions where the winters are mild it can be sown in the fall, and although the growth is slow during the winter months it will cover the ground and be ready to cut for hay or plow under as green manure in April or May, depending on the latitude and character of the season.

The winter pea has survived with very little injury temperatures of −3° F. at Washington, D. C., and −8° F. at Corvallis, Oreg., where an 8-inch snowfall afforded some protection, although the ground was frozen to a depth of 12 inches under the snow. Periods of alternate freezing and thawing are much more destructive than steady cold. Such weather during the winter and early spring has resulted in a high percentage of winterkilling in Virginia in some years.

The winter pea has been found well adapted to climatic conditions in the coastal plains of the South Atlantic and Gulf States. In this region the soils as a general rule need humus very badly. All summer-growing crops are benefited by turning under vegetable matter, and if this can be grown during the fall, winter,.and early spring months, its production does not interfere with the regular crop season. In pecan orchards also some green manure crop which will allow for summer cultivation of the orchards is desirable, as the addition of humus to the soil helps to control the rosette disease.

### Good Substitute for Hairy Vetch

The chief winter-growing legume available for this use in the Southeastern States is hairy vetch. Seed of hairy vetch is often difficult to obtain in sufficient quantities and is sometimes rather

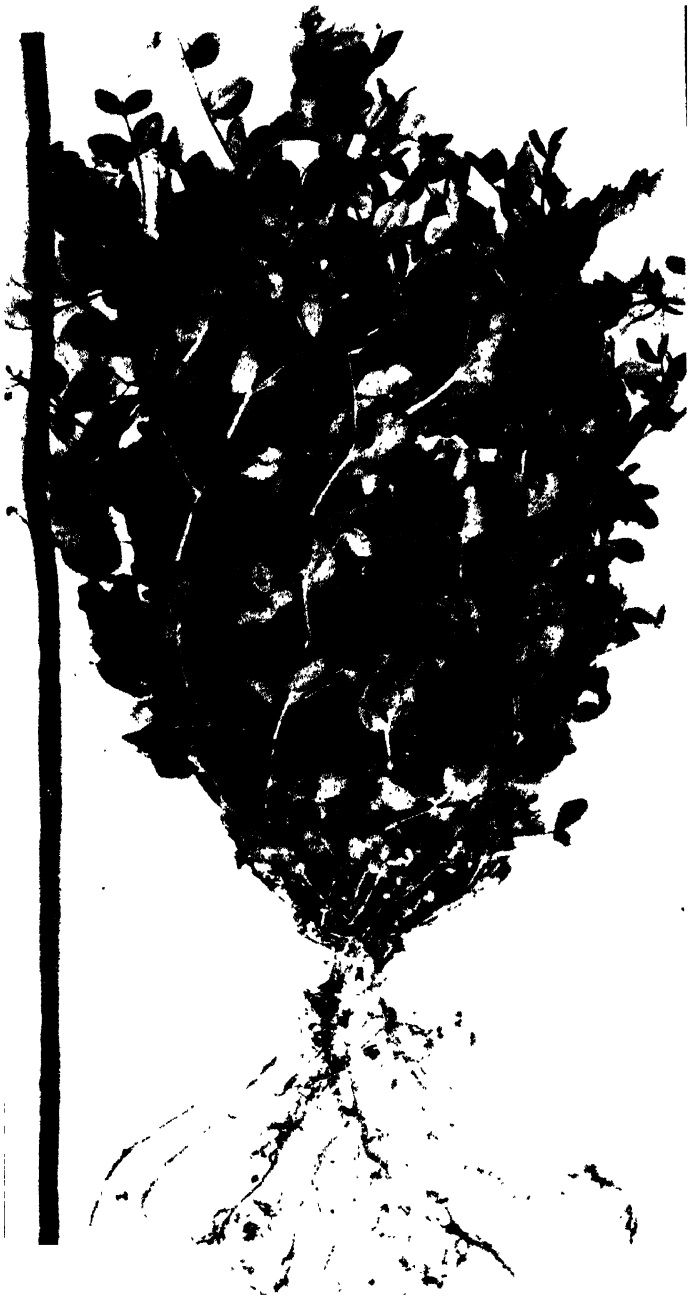

FIG. 261.—Two plants of the Austrian Winter pea and about half grown. Note the heavy stooling habit and the numerous nodules on the roots

expensive. It is desirable to have more than one crop that can be used as a winter green manure in any region, and the winter pea lends itself to this use in the Atlantic and Gulf coastal plains. Winter peas fit into the rotations fully as well as hairy vetch and make heavier yields of green matter. In the South they are fully as winter hardy also and the pea seed can be produced in the United States in almost any quantity when a steady demand for it has once been established.

The best time to sow the winter pea is between September 15 and October 15. A light seeding of rye or winter oats in mixture with the peas serves to hold them erect and by keeping them off the ground lessens their injury by disease and makes them very much easier to harvest for hay. They are seeded at the rate of 30 to 50 pounds per acre and inoculation is absolutely necessary for their successful production in the coastal plains. It has been found that they may be pastured for several months in the early spring, and if the animals are removed by April 15 or May 1 there will be considerable growth left to plow under the latter part of May.

FIG. 262.—A field of Austrian Winter peas and rye in mixture on the Arlington Experiment Farm, near Washington, D. C. Yield, green weight, 17,350 pounds per acre

An early hay crop may be obtained by sowing mixtures of winter peas and rye or peas and oats in the fall. Yields under favorable conditions often exceed 3 tons per acre, and the feeding value and palatability of the hay is very high. Ordinarily this mixture is ready to cut for hay about May 15. It should not be allowed to stand much beyond the early pod stage of maturity, otherwise it is likely to be injured by diseases and insects.

H. N. VINALL.

### WOLVES, Coyotes Take Big Toll From Stockmen

For years wolves and coyotes have been destroying western livestock and game, the losses running into millions of dollars annually. They also have been a constant menace to both domestic animals and man as carriers of rabies and other communicable diseases and parasites. A day of reckoning came. Stockmen and State officials appealed to Congress for assistance, as the animals became more destructive and their damage intolerable, in spite of local attempts to combat them. In 1915 the task was assigned to the Biological Survey of organizing and leading operations to reduce the losses inflicted by predatory wild animals.

Gradually the movement for organized control, instead of sporadic killings, gained headway, and added impetus was given it by the spread of rabies by coyotes. From 1916 to 1919 great outbreaks of this disease spread terror through the danger to human life and livestock in all States west of the Rockies. Cooperation of departments of State Governments and of stockmen's associations was enlisted by the Biological Survey and great areas of governmental and private lands were covered in an orderly way. Funds contributed annually over an 11-year period by cooperating organizations in 14 States have increased from $8,931 in the first year to $375.000 in 1925–26.

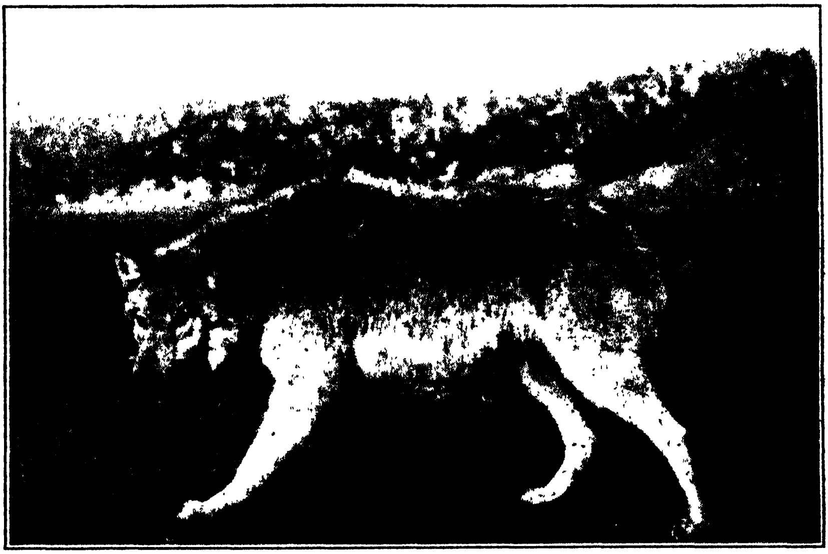

FIG. 263.—Lobo or timber wolf. These swift, powerful animals originally fed largely on buffalo, elk, and deer, but found domestic stock more to their liking and easier to kill. Losses grew so serious that it became necessary to organize a systematic campaign to clear them from livestock-producing areas

Stockmen have received demonstrations in up-to-date methods of trapping, hunting, and poisoning. Poisoning campaigns, based on a wide knowledge of conditions and improved by investigational work, are the chief reliance for destroying most of the coyotes and many of the larger wolves, and follow-up work of persistent trapping and poisoning gets individual adult survivors. Concentrating operations about lambing grounds and on pasture ranges to kill off the most destructive breeding animals has afforded real protection to livestock by cutting down the increase at the source.

Large gray, or lobo, wolves have been almost cleared from livestock ranges, and instead of occurring in large numbers and pulling down cattle and other valuable stock and game as formerly, only a few scattered individuals are now at large. When their presence is reported on the range they are promptly taken by skilled men trained in this service. A border patrol also is maintained to prevent Mexican wolves from invading southwestern ranges. During the fiscal year 1926 the destruction of 202 gray and red wolves brought the total taken in the cooperative campaigns to 6,032.

### Coyote Control More Difficult

Coyotes are more difficult to control, because of their enormous numbers and rapid reproduction, their wide distribution and aggressiveness in invading new territory, and their ability to obtain food and to survive in closely settled country. Hundreds of thousands have been killed, however, in the organized onslaughts, and over great areas stockmen now report either no losses or a small fraction of those previously suffered. This means better lamb crops, lower production costs, and more animals for market, conditions favorable to both producer and consumer.

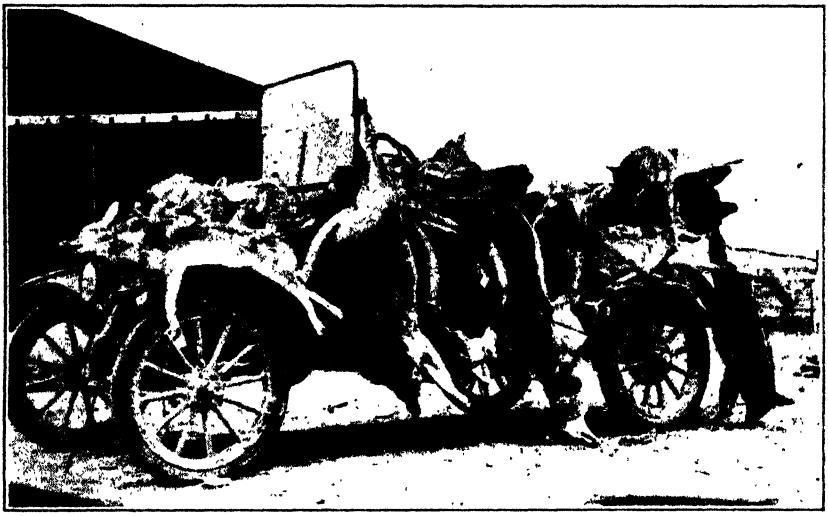

FIG. 264.—Coyotes pay the price. Countless in numbers, coyotes turned to sheep, calves, pigs, and poultry as an easily obtained food supply. The enormous losses inflicted upon stockmen and farmers made it necessary to apply vigorous, carefully planned measures for their control

The fight against wolves and coyotes will be long and arduous, but it is winning. Concerted action now eliminates major losses in two or three years' time on ordinary ranges, reduces the stock killers to occasional stragglers or invaders from neighboring territory, and under Federal leadership is steadily cutting down the possibility of reinfestation.

W. B. BELL.

**WOOD Lots Too Valuable for Pasture Use** Keep the cattle, horses, hogs, and sheep out of the farm woods in the central hardwood region, and timber will grow there just as thriftily as it ever did. If stock are not kept out the timber in the smaller farm woods appears to be doomed to slow but sure extinction.

Livestock eat and break down the young growth, bend it, strip it of bark, and tramp it out. Also by tramping the soil around the roots of older trees they pack it so tightly that air and water are excluded from the roots, and the trees gradually die. Hogs eat the seeds of oak and beech and thus interfere with the establishment of seedlings. Heavily pastured woods are easily recognized; they are almost or entirely devoid of bushy undergrowth, a sod of grass has begun to creep in, and the old trees are beginning to die in the tops.

Using the wood lot for pasture is an expensive way to raise livestock. The value of the forage grazed in a year from a woods that is at all dense is generally less than the value of the wood added in a year in a well-managed wood lot. A year's forage production is estimated to be worth from 25 cents to $1.25 an acre. In the same time a well-managed wood lot will add from one-half to 1 cord of wood. In addition there is the convenience of having a near-at-hand supply of the cordwood, poles, posts, and lumber which are constantly needed on every farm.

Livestock undoubtedly benefit from the shelter afforded by woods. Two or three acres, however, will ordinarily give them all the shelter they need; the remainder of the woods had better be fenced off to grow a wood crop.

A wood lot, like a herd of cattle, will develop in quantity, quality, and value if given common-sense treatment. If the owner of cattle were continually to sell off or kill for meat the best individuals in the herd, he would in time have on his hands only scrub animals. The farm wood lot responds in just the same way. If the best trees, such as ash, yellow poplar, black walnut, red gum, hickory, and red and white oak, are the only ones removed from the wood lot, and the inferior beech, black oak, elm, soft maple, and black gum and similar trees are left in possession of the ground, the result is bound to be scrub woods.

### Eliminating Poorer Trees

Do not sell to prospective buyers all the choice trees in the woods unless it is possible to cut out at the same time the poorer species. In cutting cordwood for home use or sale, take out the scrubby, limby, and less valuable trees, thus making the cuttings pay double by giving the valuable timber more space to grow.

Fires must be kept out of the farm woods. They kill back to the ground young trees in the brush stage or even those up to 4 or 6 inches in diameter; they burn into the larger trees at the butt, so that the value of the butt log is greatly reduced, either because of the fire scar or because rot or insects enter through the fire-caused wound. Sometimes this wound becomes so deep that the tree is broken off by the wind. In addition, fires destroy the fallen leaves, small twigs, and the partly decayed vegetable matter of the soil (the natural manure) and thus greatly impair the soil fertility.

A farm woods that has become badly run down through mistreatment, or an old field that has played out to such an extent that it will no longer grow a good field crop, can be planted to forest trees at the rate of about 1,000 to the acre. Ordinarily the softwoods, such as pine and spruce, do better on such land than the hardwoods, like oak, ash, and gum. Before selecting the kind of trees to plant, the owner should find out what others in the region have done or should ask the advice of the State forester. In Wisconsin, Michigan, Ohio, Indiana, Kansas, Kentucky, Iowa, Nebraska, Missouri, and Oklahoma, to mention only the States of the central hardwood region, small trees for forest planting can be obtained from State nurseries at a very reasonable price, on application to the State forester.

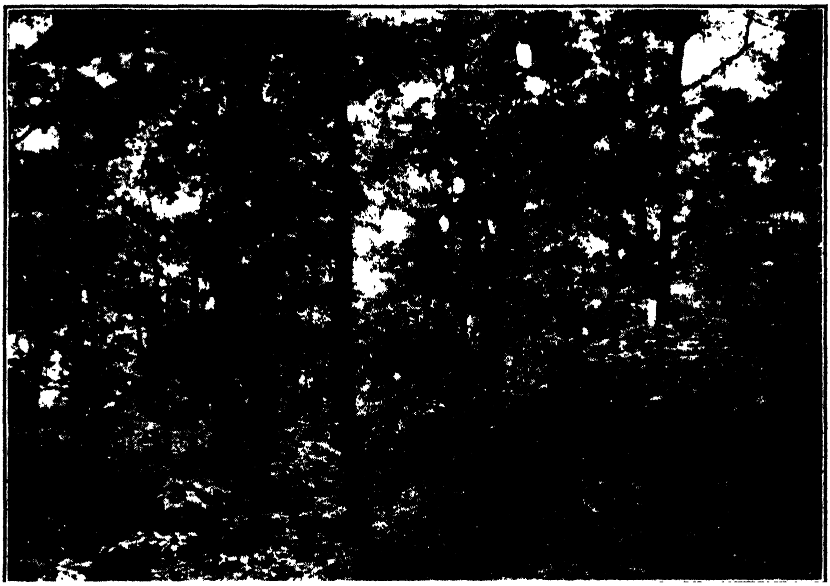

FIG. 265.—A well-managed second-growth forest uninjured by grazing animals, with plenty of reproduction and growing rapidly

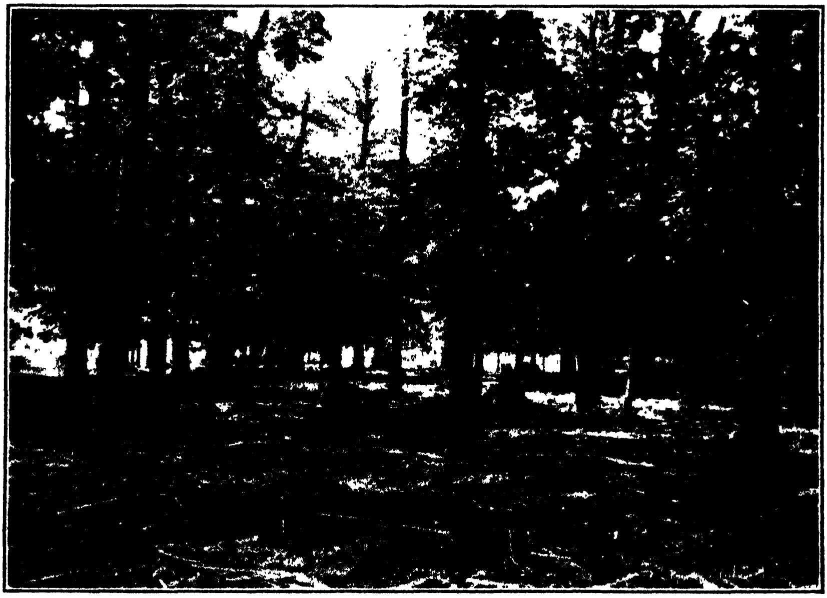

FIG. 266.—A forest in which grazing by cattle and hogs has prevented reproduction and has caused serious injury to the trees through exposure of the roots

Having brought his timber to merchantable size, the farmer who wants to get the best return for his good management will do well to consult the articles in this volume on measuring and marketing timber. Instead of selling hurriedly when an offer is made, he should make sure that he is in position to make a good sale; that he knows how much timber he has and approximately what it is worth, just as he would if he were selling hogs. Consult the State forester. It is one of his functions to assist farm woods owners in estimating and marketing timber. Timber has an advantage over other farm crops in that it does not have to be sold until the market is favorable.

C. R. TILLOTSON.

**WOOD Lots in Northeast Pay Well for Care** Most of the wood lots in the Northeast are in the condition of an untended garden; and yet growing timber needs to be kept "weeded" quite as much as any other crop. The forest products which the wood lot yields constitute one of the most important and profitable farm crops in this region.

FIG. 267.—A hardwood forest in southern New England after an improvement cutting which removed the defective, poorly formed, and mature trees. Ample space is left for the growth and development of the younger, thrifty, well-formed trees. The product of the cutting was utilized for railroad ties and charcoal

As a rule, mixed pine and hardwoods produce higher quality of material, keep the soil in better condition, and are less liable to injury from insects and disease than hardwoods alone. Where pine or mixed pine and hardwoods have been harvested, the hardwoods in the new stand are apt to suppress and kill out the slower-growing pines. The less desirable hardwoods should be cut back when the pine is 3 or 4 feet in height. If later the hardwoods again begin to overtop the pines seriously, this operation must be repeated. Not only pine should be favored in this way, but also the better hardwoods, such as ash, oak, hickory, basswood, and in some cases yellow and paper birch and sugar maple.

In older stands, where the trees appear to be crowded, the "wolf" trees, undesirable species, and all trees that are not growing well or are hindering the growth of more thrifty trees should be cut out. Experiments in New Hampshire show that 1 cord of thinnings may be removed each year from an acre of well-stocked white pine between 30 and 50 years of age with considerable advantage in the growth and quality of the remaining trees.

The way in which mature timber is cut makes a great difference in the future of the wood lot. Where the woods are even-aged their make-up should determine the method of cutting. If hardwoods prevail, clear cutting of all merchantable trees is usually satisfactory. Where pine enters considerably into the make-up of the stand, a partial cutting, removing 50 to 60 per cent of the crown canopy, is preferable. The remainder of the stand can be cut clean 4 to 6 years later, when the ground will ordinarily be amply stocked with seedlings.

### Partial Cutting Sometimes Needed

Where the trees vary considerably in age and size, partial cutting should be the rule, taking out first the largest trees, and those poorly formed, defective, and of little local value. This gives ample room for younger, thrifty, well-formed trees to put on all the wood they can.

At all times the wood lot should be protected from fire. Even light surface fires will kill small trees, decrease the fertility of the soil, and injure the larger trees. Also, all currant and gooseberry bushes, both cutivated and wild, should be pulled up anywhere within 900 feet of where white pine is to grow. Continued production of white pine is impossible unless these bushes, which are hosts for the white pine blister rust, are eradicated.

Where tree planting is desirable, white pine, red pine, and Norway spruce seedlings will do well under most conditions in this region. White pine can often be planted profitably under gray birch, provided the birch is completely removed when the pine is about 4 feet high.

Wood-lot owners in the Northeast who have tried it know that protection of the wood lot from fire, insects, and disease, careful methods of cutting, intelligent thinning of young stands, and planting of waste lands, pay dividends out of all proportion to the cost of such measures.

SAMUEL T. DANA.

---

## WOOD Lots in the Piedmont Region a Profit Source

Governor Angus McLean, of North Carolina, in a recent address said: "I do not expect to see agriculture a generally profitable industry in eastern North Carolina until the farmers supplement their agricultural production with crops of valuable timber for their uncultivated land." What is true for eastern North Carolina is generally true for the whole eastern Piedmont and coastal plain region. Farm woods can and should grow valuable crops, producing an income from the poorer or less easily tilled soils; but in order to do so they must be properly managed.

Proper treatment for all farm woods in the Piedmont region can be summed up in four rules. (1) Grow more of the more valuable trees: (2) cut the mature trees in such a way that a new crop will come in promptly; (3) by thinning the stand lightly and often, encourage the better trees to grow more rapidly; and (4) always protect the woodland from fire and from heavy grazing.

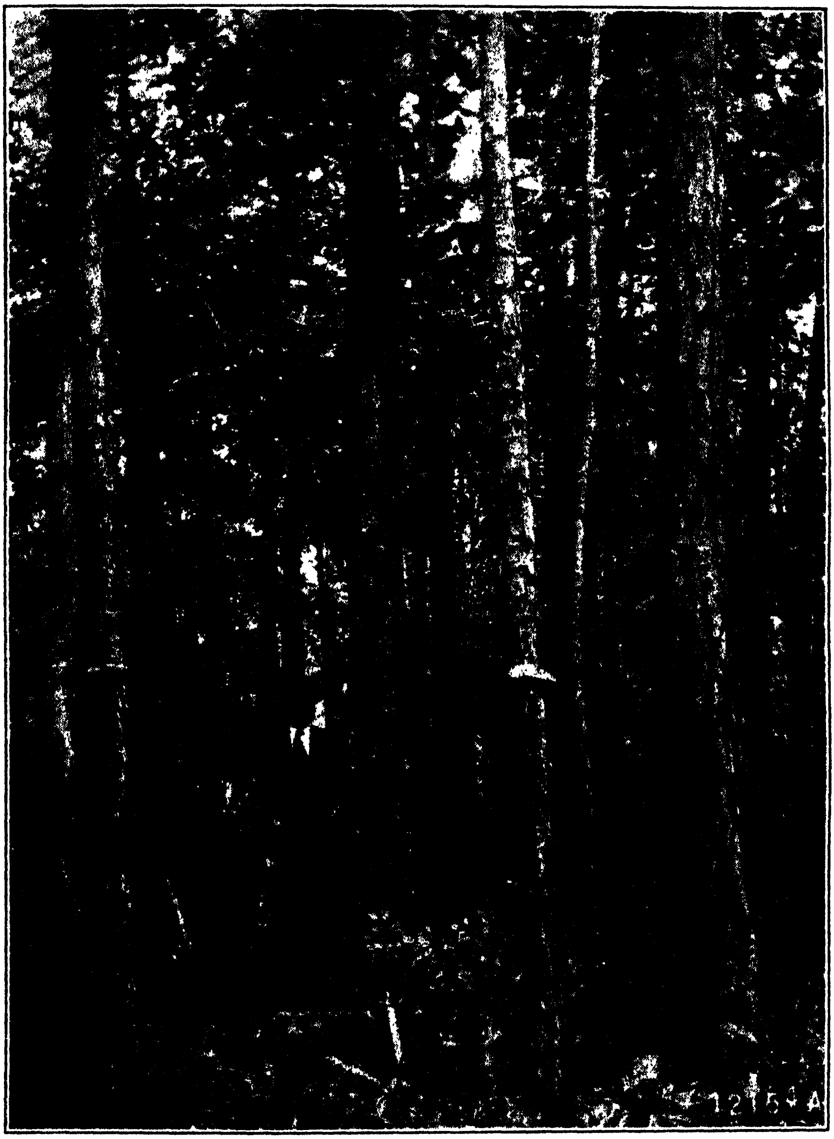

FIG. 268. A stand of mixed pine and hardwoods on the Piedmont Plateau, unburned and not grazed, but in need of a cutting to stimulate the growth of the better pines

Any owner of farm woods in determining what trees will yield him the greatest returns will choose both those which grow most rapidly to merchantable size and those which will yield the most valuable wood. Yellow poplar, loblolly pine, and sweet gum will do both, if grown on moist, well-drained soil, as at the foot of a slope. Black walnut and shagbark hickory thrive on moist soils and produce wood of high value, although their growth is slow. Drier soils will produce good yields of shortleaf pine, oaks, black locust, and pignut hickory. Trees that are both of low value and slow growth should be eliminated as rapidly as possible without breaking up the stand.

### Best Time to Weed Out

Weeding out poor species and defective trees is a continuous process, but is most effective when the stand is young. A very little work with the ax or brush hook when the trees are only a few feet high will do away with many of the so-called " weed " trees, such as sassafras, scrub oak, sumac, and dogwood. Later on, small and defective trees may be cut out for fuel. Such thinnings should leave a little space around the crowns of all the best trees in the stand, but should not be so heavy that the lower branches get light enough to live. Stands properly thinned at intervals of 5 or 10 years will develop long clear trunks and thrifty crowns capable of supporting a rapid growth.

Farm woods are subject to very serious loss from fire in the destruction of young trees and damage to older ones, and also in indirect loss through destruction of the leaf litter and organic matter in the soil. They can usually be protected from fire quite easily, however, and such protection should never be omitted.

One of the greatest sources of damage to farm woods is overgrazing, especially where livestock are kept fenced in the woods. Even where timber has grown beyond the sapling stage, it is better to have no grazing at all than to run the risk of overgrazing. Cattle do not browse on the pines, and therefore cattle grazing is not nearly so disastrous in the young pine woods of the Piedmont section as in the young hardwood timber; but if heavy grazing is permitted in very young pine stands much damage is done to the young trees by trampling.

Properly managed, the wood lot is an asset to any farm. It will provide perpetually the various kinds of wood needed in farm maintenance; it can be managed with little labor at off periods; it furnishes from time to time revenue not dependent upon season or weather; and, finally, a piece of woods adds attractiveness to the farm, and gives shade in summer and protection from cold winds and storms in winter.

E. H. FROTHINGHAM.

---

## WOOL Shrinkage Tests Important to Sheep Raisers

Wool as it comes from the sheep contains a large quantity of foreign matter, particularly when it is produced on the broad, open spaces of our western ranges. Here the sheep are exposed to severe weather conditions and the wool soon becomes very dirty. (Fig. 269.) It is not unusual to find

**fleeces in their natural condition that yield only 25 to 50 per cent clean wool, the remainder being grease, dirt, and foreign matter. Wide variations in this loss or shrinkage are a common occurrence among sheep running on the same range and even among the same sheep from one year to the next.**

Expert judgment, combined with actual tests, furnishes the men in the wool trade information regarding this shrinkage not at the command of most woolgrowers.

Although this information is vital to the man in the trade for the intelligent buying of wool and efficient production of cloth, it is also essential to the woolgrower if he hopes to attain the highest efficiency in wool production. With such knowledge at his command he can breed and manage his sheep more intelligently.

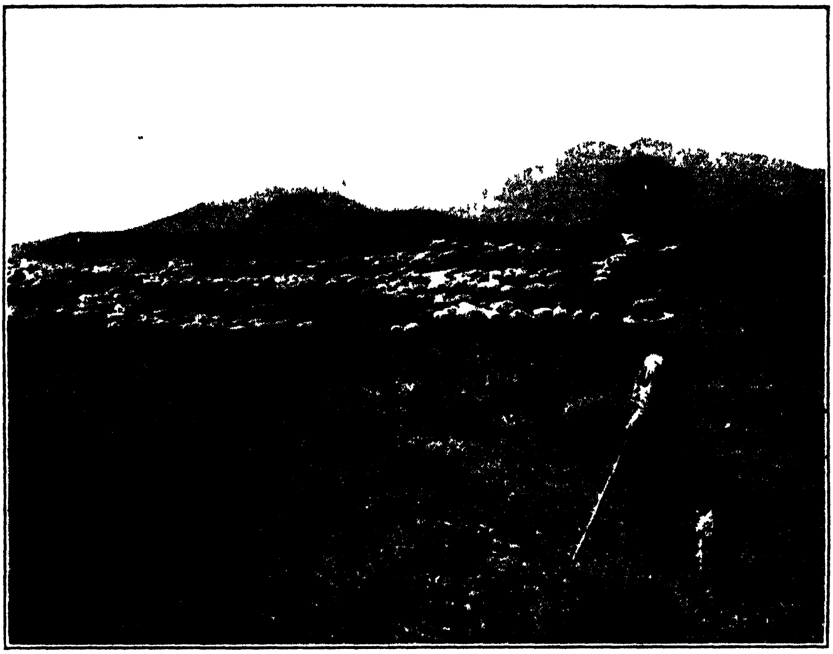

FIG 269—Sheep grazing in the Southwest The dirt and foreign matter find ready access to the wool during the wind and storm in such rough, open country

With the idea constantly in mind of helping the woolgrower in his knowledge of wool shrinkage and thereby improving methods of wool production the Bureau of Animal Industry has undertaken special investigations which are throwing more light on this question. It is endeavoring to establish a method whereby a grower may determine quickly and in a practical manner the relative clean-wool production of his sheep at his own shearing shed and with inexpensive equipment.

### Encouraging Progress Made

Such a goal may seem at first thought impossible to attain, but encouraging progress has already been made. In the examination and subsequent scouring of over 100 foreign and domestic wool samples the writer observed large differences in density of light and heavy shrinking wools. This condition was often noted in fleeces from bales of wool that had been baled under high pressure and allowed to stand for a considerable time before opening. The difference in density is much more marked under such conditions than it is when the fleeces are first sheared. These observations led to a study of the density of unscoured wool, with the hope that it might throw a new light on wool shrinkage.

The apparatus used for compressing the wool and obtaining its density is shown in Figure 270. A whole fleece is weighed and placed in the tall cylinder, where it is compressed by means of the screw until the required pressure is shown on the scale beam. The depth of the compressed wool is read directly in millimeters opposite the thin disk on top of the screw. The volume occupied by a given weight of wool under definite pressure is readily calculated from this depth. In this manner a large number of samples of wool have been compressed and subsequently tested for clean-wool content. By referring to curves prepared from a large number of these tests one obtains readily the clean-wool content on similar samples without performing the scouring operation.

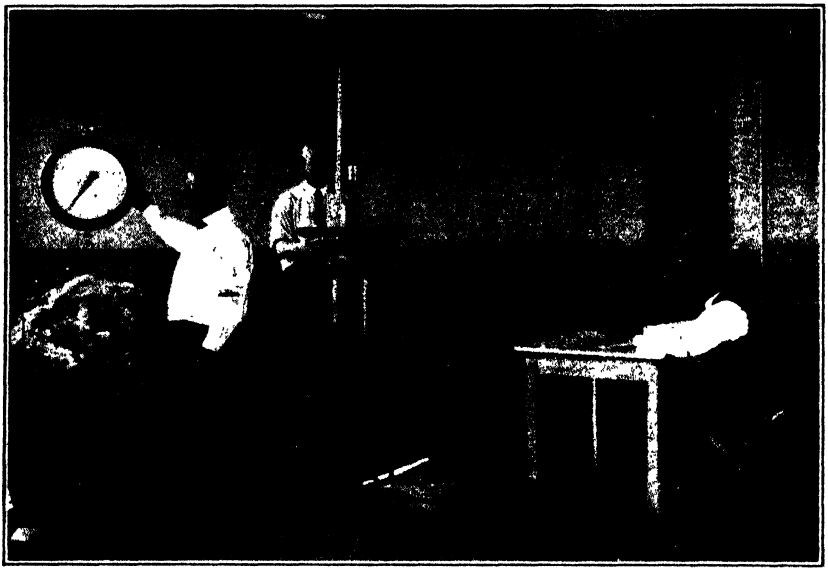

FIG. 270.—Weighing and compressing fleeces and recording results at the wool laboratory at the United States Range Livestock Experiment Station

Definite weights of light-shrinking wools of a given grade occupy much more volume than heavy-shrinking wools of the same grade.

Although there is little doubt that these tests on fleeces are valuable and offer considerable assistance in the estimation of shrinkage, just how far the tests may be refined to meet the grower's needs is a question still under investigation.

J. I. HARDY.

**WORKING Day of Farmers a High Average** Often the question is raised as to how much farmers work as compared with those in other industries. Farm-management studies undertaken in recent years by the Bureau of Agricultural Economics in cooperation with State colleges of agriculture offer interesting information on the subject. As a part of these studies a careful and complete record is kept of all work done by each member of the labor force on small groups of farms. The average number of hours worked by the farm operator and by all other workmen in some of the areas in which studies have been or are being undertaken is shown in Table 31.

TABLE 31.—*The average number of hours worked by the farm operator and all other workmen for one year in selected farming areas*

| State | Farming area | Year | Number of farms | Operator's labor | All other labor |
|---|---|---|---|---|---|
| | | | | *Hours* | *Hours* |
| Colorado | Irrigated diversified crop and sheep feeding. | 1924 | 21 | 2 590 | 5, 165 |
| Montana | Irrigated diversified crop | 1920 | 16 | 2, 831 | 2, 812 |
| Kansas | Winter wheat | 1925 | 21 | 3, 273 | 2, 237 |
| North Dakota | Spring wheat | 1925 | 22 | 3, 076 | 3, 353 |
| South Dakota | do | 1925 | 19 | 3, 008 | 3, 938 |
| Minnesota (south) | Diversified crop and livestock | 1923 | 23 | 3, 224 | 2, 505 |
| Minnesota (north) | Dairying | 1925 | 29 | 3, 242 | 3, 332 |
| Wisconsin | do | 1922 | 23 | 3, 405 | 3, 280 |
| Ohio (south) | Diversified crop and livestock | 1923 | 20 | 3, 027 | 2, 830 |
| Ohio (north) | do | 1923 | 17 | 3, 283 | 3, 590 |
| Iowa | do | 1925 | 22 | 3, 213 | 3, 629 |
| North Carolina | Tobacco and livestock | 1925 | 20 | 2, 781 | 6, 694 |
| Texas | Cotton (black-land belt) | 1925 | 19 | 2, 024 | 3, 340 |

The hours of work shown in Table 31, include only the physical labor performed. The hours shown consist of work in the fields on crops, feeding and caring for livestock and miscellaneous maintenance and repair work about the farm. In addition the farm operator performed the duties incident to the management of the farm including the supervision of the work done by other workmen. The average amount of work done by other workmen on these farms is shown also in the table.

### Some Work Much More Than Others

There is considerable variation in the number of hours worked during the year by the different farm operators. For example, one farmer in northern Minnesota worked only 848 hours, while another worked 3,948 hours. However, 25 out of the 29 farmers in this area for whom data are shown worked between 2,700 and 3,700 hours, the average for the group being 3,242 hours.

The variations in this area are fairly typical of the variations in the other areas. It should be remembered that data are included for farm operators of all ages, some of whom were supervising several other workmen. On the other hand it is possible that the farmers for whom data are shown worked more hours than the average since, as a rule, the more enterprising farmers are more likely to be interested in records of this kind.

The average number of hours worked per day by seasons in the different areas with week-day and Sunday given separately is shown in Table 32. From these data it appears that most farmers keep busy during the spring and summer—perhaps a larger number of them work on the average more than 10 hours per day than work less. Many of them also work long days in the fall—perhaps more of them work on the average longer than 9 hours per day than work less. Perhaps as many of them work 8 hours per day or more as work less during this winter period. The amount of work done during the winter season varies with the type of farming followed, being heaviest on those farms on which much livestock is kept. In addition to the week-day work, considerable farm work must be done on Sunday. This is particularly true on farms on which dairying is the principal enterprise.

### Farmers Take Occasional Holidays

It is not to be assumed from these data that farmers work every day during the year. Practically every farmer takes a day off now and then. A given farmer will work more some days than others during the same season. The data merely show the average number of hours worked considering all work days and Sundays.

TABLE 32.—*Average hours worked by farm operators by seasons, week day and Sunday separate*

| State | Winter[1] |  | Spring |  | Summer |  | Fall |  | Yearly average |  |
|---|---|---|---|---|---|---|---|---|---|---|
|  | Week day | Sunday | Week day | Sunday | Week day | Sunday | Week day | Sunday | Week day | Sunday |
|  | *Hours* | *Hours* | *Hours* | *Hours* | *Hours* | *Hours* | *Hours* | *Hours* | *Hours* | *Hours* |
| Colorado | 6.0 | 3.6 | 7.6 | 2.5 | 9.6 | 3.8 | 7.7 | 2.6 | 7.7 | 3.1 |
| Montana | 6.3 | 3.4 | 8.1 | 4.4 | 10.0 | 4.6 | 8.9 | 4.5 | 8.3 | 4.2 |
| Kansas | 8.5 | 5.2 | 10.1 | 4.7 | 10.8 | 3.7 | 9.6 | 4.2 | 9.7 | 4.4 |

| Iowa | 8.3 | 3.4 | 10.7 | 3.3 | 10.3 | 2.9 | 9.6 | 2.8 | 9.8 | 3.1 |
| North Carolina | 7.0 | 1.4 | 9.0 | 1.5 | 10.0 | 1.5 | 8.6 | 1.4 | 8.7 | 1.4 |
| Texas | 5.5 | 1.7 | 6.1 | 1.8 | 6.8 | 1.9 | 6.3 | 1.7 | 6.2 | 1.8 |

[1] The year is divided into four equal parts, with December, January, and February considered winter; the following three months, spring, etc.

J. B. HUTSON.

## WORK Time of Horses on Farm Varies Widely

In farming a considerable part of the crop area is used in producing feed for the work stock. The proportion of the total area necessary for this purpose depends to some extent upon the way in which the work stock requirements are distributed during the year. This is reflected in the average amount that each horse is worked during the year.

The hours of work per horse by seasons in selected farming areas of the United States is shown in Table 33. These data were obtained from farm-management studies undertaken in cooperation

**with State colleges of agriculture. They show the number of hours that horses were worked as taken from records carefully kept and closely supervised.**

TABLE 33.—*Hours of work per horse by seasons in selected farming areas*

| State | Area | Year | Number of farms | Winter [1] | Spring | Summer | Fall | Total |
|---|---|---|---|---|---|---|---|---|
| Colorado | Irrigated diversified crop and sheep feeding. | 1924 | 21 | 94 | 302 | 263 | 327 | 986 |
| Montana | Irrigated diversified crop | 1920 | 16 | 35 | 215 | 236 | 219 | 705 |
| Kansas | Winter wheat | 1925 | 21 | 128 | 287 | 255 | 157 | 827 |
| South Dakota | Spring wheat | 1922 | 20 | 60 | 241 | 306 | 211 | 818 |
| Minnesota | Diversified crop and dairying | 1920 | 23 | 92 | 221 | 300 | 219 | 832 |
| Wisconsin | Dairying | 1922 | 23 | 86 | 222 | 230 | 172 | 710 |
| Ohio (south) | Diversified crop and livestock | 1923 | 20 | 66 | 240 | 205 | 125 | 636 |
| Ohio (north) | do | 1923 | 17 | 86 | 211 | 264 | 150 | 711 |
| Kentucky | Tobacco and livestock | 1924 | 18 | 65 | 287 | 296 | 208 | 856 |
| North Carolina | do | 1925 | 20 | 188 | 487 | 308 | 184 | 1,167 |
| Texas | Cotton (black-land belt) | 1925 | 21 | 289 | 295 | 231 | 99 | 914 |

[1] The year is divided into four equal parts: December, January, and February are considered winter, the following three months spring, etc.

### Work is Seasonal

Generally horses are worked more in the spring and summer than in the fall and winter. As a rule, they are worked about one-third the work days during the spring and summer seasons. During the fall months perhaps one-fourth the work days is a more common practice. In winter, in most sections, perhaps less than one-tenth of the total available horse work is utilized in as many cases as more is used. In the South, because of an earlier planting, horses are usually worked more in February and March than during the fall months. This explains the large amount of horse work shown for North Carolina and Texas during the winter season. The large amount of horse work shown for Colorado in the fall is explained by the fact that potatoes and sugar beets were important crops in the area from which these data were obtained, and both require much horse work in harvesting and marketing during the fall season.

There is a wide variation in the amounts horses are worked on different farms and in different areas. Important factors in determining these differences are the length of the growing season and the system of farming being followed. For example, in a farming area in southern Ohio in 1923, the horses on 20 farms were worked on the average only 636 hours per horse, while in an area of North Carolina in 1925 the horses on 20 farms were worked on the average 1,167 hours. That is, in southern Ohio the horses were worked during the year the equivalent of 63.6 days of 10 hours each, and in North Carolina they were worked the equivalent of 116.7 days. In western Kentucky one of the 18 farmers worked his horses on the average the equivalent of 59.6 10-hour days, while another worked them the equivalent of 145.5 days. The latter followed a more diversified system than the former.

### Some Keep Too Many Horses

Often farmers keep more work horses than are required by the crops grown and other livestock kept. For example, a Colorado farmer keeping seven work horses never worked more than six of them at any one time during the year. He worked more than four only 17 days during the year. As a result, he used 20 per cent of his total crop area in producing feed for the work stock. It is to the farmer's interest to plan the crops and livestock so that the horse work requirements will be distributed as much as possible and at the same time to plan to keep only as many mature horses as are necessary to take care of these needs.

J. B. HUTSON.

# Miscellaneous Lists

## List of new Farmers' Bulletins, Department Bulletins, Department Circulars, Miscellaneous Circulars, and Statistical Bulletins issued from January 1, 1926, to December 31, 1926, classified by general subject matter

[These different types of publications are indicated by the letters preceding each serial number]

## List of Land-Grant Colleges in the United States

November, 1926

This list includes all colleges of agriculture and mechanic arts receiving the benefits of the acts of Congress of July 2, 1862, and August 30, 1890. Those marked with an asterisk (*) do not maintain courses of instruction in agriculture.

| State or Territory | Name of institution and location | President [1] |
|---|---|---|
| ALABAMA | Alabama Polytechnic Institute, Auburn | Spright Dowell. |
| | Agricultural and Mechanical Institute for Negroes, Normal | T. R. Parker. |
| ALASKA | Alaska Agricultural College and School of Mines, Fairbanks | C. E. Bunnell. |
| ARIZONA | College of Agriculture of University of Arizona, Tucson | J. J. Thornber.[2] |
| ARKANSAS | College of Agriculture of University of Arkansas, Fayetteville | D. T. Gray.[2] |
| | State Agricultural, Mechanical and Normal School, Pine Bluff | R. E. Malone.[3] |
| CALIFORNIA | College of Agriculture of University of California, Berkeley | E. D. Merrill.[2] |
| COLORADO | State Agriculture College of Colorado, Fort Collins | C. A. Lory. |
| CONNECTICUT | Connecticut Agricultural College, Storrs | C. L. Beach. |
| DELAWARE | School of Agriculture, University of Delaware, Newark | C. A. McCue.[2] |
| | State College for Colored Students, Dover | R. S. Grossley. |
| FLORIDA | College of Agriculture of University of Florida, Gainesville | Wilmon Newell.[2] |
| | Florida Agricultural and Mechanical College for Negroes, Tallahassee. | J. R. E. Lee. |
| GEORGIA | Georgia State College of Agriculture, Athens | A. M. Soule. |
| | Georgia State Industrial College, Savannah | B. F. Hubert. |
| HAWAII | University of Hawaii, Honolulu | A. L. Dean |
| IDAHO | College of Agriculture of University of Idaho, Moscow | E. J. Iddings.[2] |
| ILLINOIS | College of Agriculture of University of Illinois, Urbana | H. W. Mumford.[2] |
| INDIANA | School of Agriculture of Purdue University, LaFayette | J. H. Skinner [2] |
| IOWA | Iowa State College of Agricultural and Mechanic Arts, Ames | |
| KANSAS | Kansas State Agricultural College, Manhattan | F. D. Farrell |
| KENTUCKY | College of Agriculture of University of Kentucky, Lexington | T. P. Cooper.[2] |
| | Kentucky State Industrial College, Frankfort | G. P. Russell. |
| LOUISIANA | Louisiana State University and Agricultural and Mechanical College, Baton Rouge. | T. D. Boyd. |

| | The Colored Normal, Industrial, Agricultural, and Mechanical College of South Carolina, Orangeburg. | R. S. Wilkinson. |

[1] The name of the dean of the college of agriculture is given where that college is a part of a university.
[2] Dean.
[3] Superintendent.
[4] Principal.
[5] Director.

## List of Land-Grant Colleges in the United States—Continued

| State or Territory | Name of institution and location | President [1] |
|---|---|---|
| **SOUTH DAKOTA** | South Dakota State College of Agriculture and Mechanic Arts, Brookings. | C. W. Pugsley. |
| **TENNESSEE** | College of Agriculture of University of Tennessee, Knoxville | C. A. Willson.[2] |
| | Tennessee Agricultural and Industrial State College, Nashville | W. J. Hale. |
| **TEXAS** | Agricultural and Mechanical College of Texas, College Station | T. O. Walton. |
| | Prairie View State Normal and Industrial College, Prairie View | W. R. Banks.[4] |
| **UTAH** | Agricultural College of Utah, Logan | E. G. Peterson. |
| **VERMONT** | College of Agriculture of University of Vermont, Burlington | J. L. Hills.[2] |
| **VIRGINIA** | Virginia Agricultural and Mechanical College and Polytechnic Institute, Blacksburg. | J. A. Burruss. |
| | Virginia Normal and Industrial Institute, Ettricks | J. M. Gandy. |
| **WASHINGTON** | State College of Washington, Pullman | E. O. Holland. |
| **WEST VIRGINIA** | College of Agriculture of West Virginia University, Morgantown | H. G. Knight.[2] |
| | West Virginia Collegiate Institute, Institute | J. W. Davis. |
| **WISCONSIN** | College of Agriculture of University of Wisconsin, Madison | H. L. Russell.[2] |
| **WYOMING** | College of Agriculture of University of Wyoming, Laramie | J. A. Hill.[2] |

[2] Dean.

[4] Principal.

## List of Agricultural Experiment Stations in the United States

November, 1926

This list gives the post-office addresses of the agricultural experiment stations in the United States, followed by the name of the director or other officer in charge:

**ALABAMA**—
(College station), Auburn: M. J. Funchess.
(Canebrake station), Uniontown: W. A. Cammack.
(Tuskegee station), Tuskegee Institute: G. W. Carver.
**ALASKA**—Sitka: C. C. Georgeson.
**ARIZONA**—Tucson: J. J. Thornber.
**ARKANSAS**—Fayetteville: D. T. Gray.
**CALIFORNIA**—Berkeley: E. D. Merrill.
**COLORADO**—Fort Collins: C. P. Gillette.
**CONNECTICUT**—
State station, New Haven }
Storrs station, Storrs } W. L. Slate, jr.
**DELAWARE**—Newark: C. A. McCue.
**FLORIDA**—Gainesville: Wilmon Newell.
**GEORGIA**—
(State station), Experiment: H. P. Stuckey.
(Coastal Plain station), Tifton: S. H. Starr.
**GUAM, ISLAND OF**—Guam: C. W. Edwards.
**HAWAII**—
(Federal station), Honolulu: J. M. Westgate.
(Sugar Planters' station), Honolulu: H. P. Agee.
**IDAHO**—Moscow: E. J. Iddings.
**ILLINOIS**—Urbana: H. W. Mumford.
**INDIANA**—La Fayette: G. I. Christie.
**IOWA**—Ames: C. F. Curtiss.
**KANSAS**—Manhattan: L. E. Call.
**KENTUCKY**—Lexington: T. P. Cooper.
**LOUISIANA**—
State station, Baton Rouge }
Sugar station, Baton Rouge }
North Louisiana station, Calhoun } W. R. Dodson
Rice station, Crowley }
Fruit and Truck station, Hammond }
**MAINE**—Orono: W. J. Morse.
**MARYLAND**—College Park: H. J. Patterson.
**MASSACHUSETTS**—Amherst: S. B. Haskell.
**MICHIGAN**—East Lansing: R. S. Shaw.
**MINNESOTA**—University Farm, St. Paul: W. C. Coffey.
**MISSISSIPPI**—A. and M. College: J. R. Ricks
**MISSOURI**—
(College station), Columbia: F. B. Mumford.
(Fruit station), Mountain Grove: F. W. Faurot.
(Poultry station), Mountain Grove: T. W. Noland.
**MONTANA**—Bozeman: F. B. Linfield.
**NEBRASKA**—Lincoln: E. A. Burnett.
**NEVADA**—Reno: S. B. Doten.
**NEW HAMPSHIRE**—Durham: J. C. Kendall.
**NEW JERSEY**—New Brunswick: J. G. Lipman.
**NEW MEXICO**—State College: Fabian Garcia.
**NEW YORK**—
State station, Geneva: }
Cornell station, Ithaca: } R. W. Thatcher.
**NORTH CAROLINA**—State College Station, Raleigh: R. Y. Winters.
**NORTH DAKOTA**—State College Station, Fargo: P. F. Trowbridge.

OHIO—Wooster: C. G. Williams.
OKLAHOMA—Stillwater: C. T. Dowell.
OREGON—Corvallis: J. T. Jardine.
PENNSYLVANIA—
    (College station), State College: R. L. Watts.
    (Institute of Animal Nutrition), State College: E. B. Forbes.
PORTO RICO—
    (Federal station), Mayaguez: D. W. May.
    (Insular station), Rio Piedras: F. A. Lopez Dominguez.
RHODE ISLAND—Kingston: B. L. Hartwell.
SOUTH CAROLINA—Clemson College: H. W. Barre.
SOUTH DAKOTA—Brookings: J. W. Wilson.
TENNESSEE—Knoxville: C. A. Mooers.
TEXAS—College Station: A. B. Conner.[1]
UTAH—Logan: William Peterson.
VERMONT—Burlington: J. L. Hills.
VIRGINIA—
    (College station), Blacksburg: A. W. Drinkard, jr.
    (Truck station), Norfolk: T. C. Johnson.
VIRGIN ISLANDS, U. S. A.—St. Croix: J. B. Thompson.
WASHINGTON—
    (College station), Pullman: E. C. Johnson.
    (Western Wash. station), Puyallup: J. W. Kalkus.[2]
WEST VIRGINIA—Morgantown: H. G. Knight.
WISCONSIN—Madison: H. L. Russell.
WYOMING—Laramie: J. A. Hill.

## National Forests

June 30, 1926

| Forest | State in which located | Net area | Forest | State in which located | Net area |
|---|---|---|---|---|---|
| | | *Acres* | | | *Acres* |
| Absaroka | Montana | 851,046 | Dix | New Jersey | 6,785 |
| Alabama | Alabama | 105,534 | Dixie | Nevada and Utah | 851,854 |

## Federal Bird Refuges and Game Preserves

DEPARTMENT OF AGRICULTURE

| Designation | Number on map | Acres | Chief species protected |
|---|---|---|---|
| *Biological Survey* | | | |
| ALABAMA: | | | |
| Petit Bois Island | 63 | 635 | Laughing gulls, least terns, black skimmers, Louisiana herons. |
| ALASKA: | | | |
| Aleutian Islands | | | Puffins, auklets, murres, gulls, ducks, geese, ptarmigan, blue foxes. |
| Bering Sea | | | Puffins, auklets, kittiwakes, glaucous gulls, sandpipers, snow buntings. |
| Bogoslof | | | Sea lions, auklets, murres, gulls. |
| Chamisso Island | | | Horned puffins, Pallas murres, Pacific kittiwakes, glaucous gulls. |
| Forrester Island | | | Puffins, auklets, murrelets, murres, guillemots, gulls, petrels, cormorants. |
| Hazy Islands | | | Puffins, auklets, murres, guillemots, gulls, cormorants. |
| St. Lazaria | | | Puffins, auklets, murres, guillemots, gulls. petrels, cormorants. |
| Tuxedni | | | Various sea birds. |

## Federal Bird Refuge and Game Preserves—Continued

### DEPARTMENT OF AGRICULTURE—Continued

| Designation | Number on map | Acres | Chief species protected |
|---|---|---|---|
| ARIZONA: | | | |
| Salt River | 27 | 21,120 | Cormorants, white pelicans, waterfowl. |
| ARKANSAS: | | | |
| Big Lake | 70 | 7,774 | Ducks of many species. |
| CALIFORNIA: | | | |
| Clear Lake | 52 | 33,840 | Gulls, cormorants, ducks, geese, herons. |
| Farallon | 49 | | Puffins, auklets, guillemots, murres, gulls, cormorants. |
| FLORIDA: | | | |
| Brevard | 77 | 12 | Brown pelicans. |
| Caloosahatchee | 73 | | Ducks, herons |
| Indian Key | 7 | 90 | Pelicans, white ibises, egrets, Louisiana and little blue herons. |
| Island Bay | 24 | | Brown pelicans, herons. |
| Key West | 17 | | Cormorants, pelicans, man-o'-war birds, roseate spoonbills, white ibises, herons. |
| Matlacha Pass | 23 | | Cormorants, pelicans, herons. |
| Mosquito Inlet | 15 | | Least terns, pelicans, herons. |
| Palma Sola | 22 | | Man-o'-war birds, herons. |
| Passage Key | 6 | 5 | Laughing gulls, terns, skimmers, cormorants, sandpipers. |
| Pelican Island | 1 | 6 | Brown pelicans. |
| Pine Island | 21 | | Pelicans, herons. |
| Tortugas Keys | 16 | 141 | Sooty and noddy terns. |
| GEORGIA: | | | |
| Blackbeard Island | 66 | 1,600 | White-tailed deer, raccoons, opossums, herons, cranes. |
| HAWAII: | | | |
| Hawaiian Islands | | | Terns, albatrosses, shearwaters, petrels, gannets, man-o'-war birds, Laysan teal, rails, and finches |
| Johnston Island | | | Sooty and noddy terns, shearwaters, petrels, boobies, man-o'-war birds. |
| IDAHO: | | | |
| Deer Flat | 29 | 12,300 | Ducks, geese, pheasants. |
| Minidoka | 43 | 13,240 | Grebes, Forster terns, cormorants, ducks, coots, avocets, sage hens. |
| ILLINOIS: | | | |
| Upper Mississippi River Wild Life and Fish Refuge (see Minnesota). | (1) | | |
| IOWA: | | | |
| Upper Mississippi River Wild Life and Fish Refuge (see Minnesota). | (1) | | |
| LOUISIANA: | | | |
| Breton Island | 2 | | Laughing gulls, royal and Cabot terns, skimmers, herons, willets |
| East Timbalier | 14 | 63 | Gulls, Royal terns, skimmers, pelicans, herons, clapper rails. |
| Shell Keys | 9 | | Royal terns, brown pelicans, man-o'-war birds |
| Tern Islands | 8 | | Laughing gulls, royal, Cabot, and Forster terns, brown pelicans. |
| MICHIGAN: | | | |
| Huron Islands | 4 | 83 | Herring gulls, ducks. |
| Siskiwit Islands | 5 | 9 | Do. |
| MINNESOTA: | | | |
| Mille Lacs | 69 | 7 | Gulls, ducks, geese. |
| Upper Mississippi River Wild Life and Fish Refuge (in the States of Illinois, Iowa, Minnesota, and Wisconsin). | (1) | | |
| MONTANA: | | | |
| National Bison Range | 16½ | 18,522 | Buffalo, elk, deer, mountain sheep, grouse, pheasants |
| Nine Pipe | 74 | | Ducks, coots. |
| Pablo | 75 | | Do |
| Pishkun | 58 | 3,160 | Gulls, ducks, geese, swans. |
| Willow Creek | 30 | 3,200 | Ducks, geese. |
| NEBRASKA: | | | |
| Niobrara | 55 | 16,125 | Buffalo, elk, deer, antelope, prairie chickens, sharptailed grouse. |
| North Platte | 72 | 5,107 | Ducks, geese, swans, shorebirds. |
| NEVADA: | | | |
| Anaho Island | 64 | 248 | Gulls, cormorants, white pelicans. |
| NEW MEXICO: | | | |
| Carlsbad | 31 | 18,680 | Ducks, shorebirds. |
| Rio Grande | 32 | 55,680 | Grebes, cormorants, ducks, geese, shorebirds. |

# AGRICULTURAL STATISTICS

## UNITED STATES DEPARTMENT OF AGRICULTURE YEARBOOK, 1926

**Prepared under the direction of the Statistical Committee: W. F. Callander, Lewis B. Flohr, Joseph A. Becker, and G. B. L. Arner**

## INTRODUCTION

Statistics of acreage, yield per acre, and production in the United States are estimates made by the Division of Crop and Livestock Estimates. For the year 1909, acreages are as reported by the Bureau of the Census; acreages in 1919 and in 1924 are based upon the census, (preliminary for 1924 in some States) supplemented by State enumerations. In the intercensal years, from 1911 to 1915, estimated acreages were obtained by applying estimated percentages of decrease or increase to the published acreage in the preceding year. The estimates from 1915 to 1918, from 1919 to 1923, and for 1925 and 1926 are based upon acreage changes from year to year as shown by a sample of approximately 2 per cent of the crop acreages in each year, supplemented by State enumerations. Yields per acre are estimates based upon reports of one or more farmers in each agricultural township on the average yield per acre in their localities. Production is acreage times yield per acre. Production estimates are in some cases revised in the following year on the basis of State enumerations and records of shipments.

Estimates of farm stocks, shipments, quality, crop condition, and miscellaneous information concerning crops are based either upon sample data or upon estimates of crop reporters for their localities. The sources of these data are indicated in the notes accompanying the tables.

Estimated prices received by producers on the specified dates are based upon reports of farmers and country dealers on the average price paid to farmers and do not relate to any specified grade. Farm value as shown is computed by applying the December 1 farm price to the total production. The average price received for the portion of the crop sold may be greater or less than this price, depending upon the price changes previous and subsequent to December 1 and the amount of the crop sold at the different prices.

Numbers of livestock on farms in 1910 correspond to the census enumeration as of April 15 in that year. The numbers on January 1, 1920 and 1925, are based upon the census enumeration (preliminary for 1925 in some States) as of that date, supplemented by enumerations by State agencies, such as assessors and brand inspection boards and by records of shipments during 1920 and 1925. In the intercensal years, from 1911 to 1916, the numbers of livestock were obtained by methods identical with those used for crop acreages. Estimates from 1917 to 1919, from 1920 to 1923, and for 1926 and 1927 are based upon a sample of approximately 2 per cent, supplemented by trends derived from assessors' enumerations, reports of brand inspection boards, market movements, and stockyard receipts. The census bases are not always comparable from one decade to another, due both to changes of dates and classifications.

The average value per head on January 1 is estimated from reports of correspondents relating to livestock in their vicinity. These are inventory values as distinguished from the monthly prices which relate to sales. The farm value on January 1 is computed by applying the average value per head to the number of head on farms.

Certain statistics represent enumerations made by the department in connection with the administration of regulatory and inspection laws. Certain other statistics represent enumerations made by the department in compliance with general legislation authorizing the collection and dissemination of information on agricultural products.

Statistics relating to supplies, movements, and market prices of agricultural products in the United States are derived from official sources as far as available; otherwise from reliable unofficial sources. In all cases wherein the data presented did not cover the field or a major sample thereof, data most representative of the various commodities, movements, and markets have been selected.

With some crops marketing and movement into consumptive channels takes place entirely within the calendar year in which the crop was produced. For many crops marketing takes place during portions of two calendar years. For a few crops, as potatoes, marketing extends beyond a 12-month period. In order that the movement and prices of the particular crop may be followed through, the months in which the crop moved have been used as the "year." Estimated prices received by producers are indices of price trends rather than prices actually received.

Weighted averages of prices are shown in all cases where a weighting factor was available. For instance, the weighted price of wheat in Chicago is based on the number of carload sales reported, which range from 42 to 55 per cent of all receipts on that market. In the case of hogs at Chicago, the weighted average price is based on total sales of butcher hogs to slaughterers. With many commodities, however, data as to quantities sold are unobtainable; in all such cases average prices are based on price quotations without reference to quantity.

It should be remembered that, due to changes in market conditions or quality of delivery in different years on or under the same grade description or specifications, prices derived from different sources may not be strictly comparable, although for most general purposes they are entirely satisfactory. For instance, the changes in the description of many kinds of livestock which were made July 1, 1925, while not affecting certain price series, made others only fairly comparable and made comparison impossible in other cases. The data as to commercial stocks and movements of various commodities are as nearly complete as practicable and feasible, and are considered fairly representative.

Data originating with other departments and agencies are included because of their general interest to the agricultural industry. The sources of such data are given in connection with the tables. Care has been taken to quote only such sources as are generally considered reliable.

Statistics of acreage and production in foreign countries are compiled as far as possible from official sources and are therefore subject to whatever errors may result from shortcomings in the reporting and statistical services of the various countries. Inaccuracies also result from differences in nomenclature and classification in foreign countries, and through the conversion of foreign units into domestic equivalents. Except where otherwise stated, pre-war data refer to pre-war boundaries. Yields per acre are calculated from acreage and production, both rounded to thousand units, and are therefore subject to a greater possibility of error when calculated for countries with small acreage.

The tables of international trade cover substantially the international trade of the world. The total imports and the total exports in any one year can not be expected to balance, although disagreements tend to be compensated over a series of years. Among the sources of disagreement are: The different periods covered by the "year" of various countries; imports received in the year subsequent to the year of export; lack of uniformity in classification of goods as among countries; different trade practices and varying degrees of failure in recording countries of origin and ultimate destination; different practices in recording reexported goods; and different methods of treating free ports. The exports given are domestic exports and the imports given are imports for consumption, whenever it is possible to distinguish such imports from general imports. While there are some inevitable omissions, there may be some duplication because of reshipments which do not appear as such in the official reports. In the trade tables, figures for the United States include Alaska, Porto Rico, and Hawaii, but not the Philippine Islands.

Since the statistics for the current year are in many cases preliminary and subject to revision on the basis of later and fuller information, the reader is cautioned to use always the figures as they appear in the latest issue of the Yearbook. For many commodities, long-time tables appear in the Statistical Bulletin series of the department. Current information gathered by the department may be found in the current issues of "Crops and Markets," "Foreign Crops and Markets," and in various mimeographed or multigraphed releases. Current information gathered by other governmental agencies and by private agencies may be found in the current issues of reports by those agencies.

## STATISTICS OF GRAINS

### WHEAT

Division of Statistical and Historical Research. For each year is shown the production during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere. Estimates of world wheat production for the period 1890–1908 appear in Agriculture Yearbook, 1924, p. 569.

[1] Includes all Russian territory reporting for years named

[2] Total Russian Empire exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.

[3] Exclusive of Russian Poland, Lithuania, parts of present Latvia and Ukraine, and 2 Provinces of Transcaucasia.

[4] Estimated production within present boundaries of the Union of Socialist Soviet Republics, excluding Turkestan, Transcaucasia, and the Far East, which regions in 1924 produced 51,706,000 bushels, and in 1925, 58,000,000 bushels.

[5] Production within postwar boundaries and therefore not comparable with earlier years.

[6] Preliminary.

[1] Where changes in boundary have occurred, averages are estimates for territory within present boundaries.
[2] Two-year average.
[3] Four-year average.
[4] Three-year average.
[5] One year only.
[6] Revised estimates for all Russia distributed between European and Asiatic territory in the same ratio as the preliminary estimate.
[7] The estimate for the 5-year period, 1909–1913, given in this table is somewhat larger than the figures obtained by averaging those 5 years in Table 9. This is because in the detailed table estimates for warring countries are for post-war boundaries, whereas in Table 9 they are for pre-war territory. As a result in excluding Russia, which lost territory in the war, a smaller area is excluded in the detailed table than in Table 9.

TABLE 9.—*Wheat: Acreage, yield per acre, and production in specified countries, average 1909–1913, 1921–1925, annual 1924–1926*—Continued

Division of Crop and Livestock Estimates. Prior to 1918 stocks in mills and elevators not included.

[1] Based on percentage of crop as estimated by about 3,500 mill and elevator operators.
[2] Based on percentage of crop on farms as estimated by crop reporters.
[3] Based on estimates of crop reporters on Nov. 1.
[4] Percentage of "a high medium grade" as estimated by crop reporters at time of harvest.
[5] Based on percentage shipped out as estimated by crop reporters.
[6] Preliminary.

Division of Statistical and Historical Research. Compiled from Monthly Summary of Foreign Commerce of the United States, and official records of the Bureau of Foreign and Domestic Commerce.

[1] Includes exports of flour milled from Canadian wheat imported in bond. Does not include reexports. Flour has been converted to grain on the following basis. 1909–1917, 1 barrel of flour is the product of 4.7 bushels of grain; 1918 and 1919, 4.5 bushels; 1920, 4.6 bushels; and 1921–1926, 4.7 bushels.

Division of Statistical and Historical Research. Compiled from official records of the Bureau of Foreign and Domestic Commerce.

[1] Barrels of wheat flour converted to bushels of grain on the basis of 1 barrel=4.7 bushels.

[2] Includes Montana and Idaho, Dakota, Duluth and Superior, Wisconsin, Michigan, Chicago, Vermont, St. Lawrence, Buffalo, Ohio, and Minnesota.

[3] Includes Maine and New Hampshire, New York, Philadelphia, Maryland, Virginia, South Carolina, Georgia, Porto Rico, Connecticut, Rhode Island, and Massachusetts.

[4] Includes Florida, Mobile, New Orleans, Sabine, and Galveston.

[5] Includes Arizona, San Antonio, and El Paso.

[6] Includes San Diego, Los Angeles, San Francisco, Oregon, Washington, Alaska, and Hawaii.

TABLE 18.—*Wheat: Production and inspection for export, by classes, United States, average 1921–1925, annual 1923–1925, and July-December, 1926*

[Thousand bushels—i. e., 000 omitted]

| Total | 804,148 | 203,164 | 797,381 | 156,430 | 864,428 | 250,023 | 676,429 | 108,035 | 832,305 | 146,560 |

Division of Statistical and Historical Research for estimated production by classes; Grain Division for inspections of United States wheat for export. Data, 1921 and 1922, available in 1925 Yearbook, page 762, Table 17.

[1] The spring and winter wheats listed do not include the spring and winter in the white wheats. Production estimates are based on the estimate of percentage classification by States as reported for 1920 and 1923 to the Division of Crop and Livestock Estimates; the percentages for 1921 and 1922 were interpolated from the 1920 and 1923 percentages. The estimated production for 1925 and 1926 is subject to revision.

[2] White wheat in the Pacific Northwest region consists of both spring and winter wheat; no attempt has been made to classify this wheat as other than white wheat, part of which is spring and part winter.

[3] From July 1, 1921, to June 30, 1923, 70 per cent of the exports of mixed wheat is estimated as durum.

[4] Exports of wheat other than reported as "Federal inspected," including exports through Canada.

Division of Statistical and Historical Research. Compiled from daily trade papers of markets named.

---

[1] The prices in this table are comparable with farm prices in that the farm prices are averages of the several prices reported which cover all classes and grades sold from the farm.

[2] Average of daily prices weighted by car-lot sales.

[3] Markets are Chicago, Minneapolis, Kansas City, and St. Louis.

[1] Where changes in boundary have occurred averages are estimates for territory within present boundaries.
[2] Three-year average.
[3] Four-year average.
[4] Estimated on the basis of acreage reported and an average yield of 8.9 bushels to the acre.

TABLE 35.—*Rye: Acreage, yield per acre, and production in specified countries, average 1909–1913, 1921–1925, annual 1924–1926*—Continued

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture except as otherwise stated. Figures are for crops harvested during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere.

Where changes in boundary have occurred averages are estimates for territory within present boundaries.

[2] Three-year average.

[3] Four-year average.

[5] Revised estimate apportioned between European and Asiatic Russia at the same ratio as the preliminary estimate.

[6] The estimate for the 5-year period, 1909–1913, given in this table is somewhat larger than the figure obtained by averaging those 5 years in Table 36. This is because in the detailed table estimates for warring countries are for post-war boundaries, whereas in Table 36 they are for pre-war territory. As a result, in excluding Russia, which country lost territory in the war, a smaller area is excluded in the detailed table than in Table 36.

[7] One year only.

[8] Two-year average

### TABLE 36.—*Rye: World production, 1909–1926*

Division of Statistical and Historical Research. For each year is shown the production during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere. Estimates of world rye production for the period 1894–1908 appear in Agriculture Yearbook, 1924, p. 596.

[1] Includes all Russian territory reporting for the years shown.

[2] Exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.

[3] Exclusive of Russian Poland, Lithuania, parts of Latvia and the Ukraine, and the two Provinces of Batum and Elizabethpol in Transcaucasia.

[4] Estimate for the present territory of the Union of Socialist Soviet Republics exclusive of Turkestan, Transcaucasia, and the Far East, which territory in 1924 produced 8,646,000 bushels.

[5] Present boundaries, therefore not comparable with earlier years.

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture. Figures refer to the crop harvested in the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere.

[1] Where changes in boundary have occurred, the averages reported are estimates for the crop within present boundaries.

[2] One year only.

[3] Two-year average.

[4] Four-year average.

[5] The estimate for the five-year period, 1909-1913, given in this table is somewhat larger than the figure obtained by averaging those five-year periods in Table 48. This is because in the detailed table estimates for warring countries are for post-war boundaries, whereas in Table 48 they are for pre-war territory. As a result in excluding Russia, which lost territory in the war, a smaller area is excluded in the detailed table than in Table 48.

[6] Includes some sorghum

[7] Rough preliminary estimate assuming that countries not yet reporting produce an average crop.

## TABLE 48.—*Corn: World production, 1909–1926*

Division of Statistical and Historical Research. For each year is shown the production during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere. Estimates of world corn production for the period 1900–1908 appear in Agriculture Yearbook, 1924, p. 606.

[1] Includes all Russian territory reporting for the years shown.

[2] Exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.

[3] Exclusive of Russian Poland, Lithuania, parts of Latvia and the Ukraine, and the two Provinces of Batum and Elizabethpol in Transcaucasia.

[4] Estimate for the present territory of the Union of Socialist Soviet Republics, exclusive of Turkestan, Transcaucasia, and the Far East, which territory in 1924 produced 26,048,000 bushels.

[5] Production in present boundaries, therefore not comparable with earlier years.

[6] Preliminary.

Division of Crop and Livestock Estimates.

[1] Based on reported percentage of entire crop on farms, proportion merchantable, and per cent shipped out of county where grown.

[2] 1909–10 to 1920–21, quality reported as per cent of a high medium grade; 1921–1926, per cent of merchantable quality.

[3] Preliminary.

TABLE 51.—*Corn: Receipts at primary markets, averages by groups, 1909–1925, and annual, 1921–1925*

[Thousand bushels—i. e , 000 omitted]

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture except as otherwise stated. Figures given are for crops harvested during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere.

[1] Where changes in boundary have occurred, the averages are estimates for territory within present boundaries.

[2] Four-year average.

[3] One year only.

[4] Three-year average.

[5] The estimate for the five-year period, 1909–1913, given in this table is somewhat larger than the figure obtained by averaging those five years in Table 65. This is because in the detailed table estimates for warring countries are for post-war boundaries, whereas in Table 65 they are for pre-war territory. As a result, in excluding Russia, which lost territory in the war, a smaller area is excluded in the detailed table than in Table 65.

[6] Two-year average

[7] Estimates for all Russia distributed between European and Asiatic territory in the same ratio as the 1925 preliminary estimate.

## TABLE 65.—*Oats: World production, 1909–1926*

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture. For each year is shown the production during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere. Estimates of world oats production for the period 1894–1908 appear in Agriculture Yearbook, 1924, p. 622.

[1] Includes all Russian territory reporting for the years shown.

[2] Total Russian Empire exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.

[3] Exclusive of Russian Poland, Lithuania, parts of Latvia and the Ukraine, and the two Provinces of Batum and Elizabethpol in Transcaucasia.

[4] Estimate for the present territory of the Union of Socialist Soviet Republics exclusive of Turkestan, Transcaucasia, and the Far East, which territory in 1924 produced 20,248,000 bushels.

[5] Present boundaries, therefore not comparable with earlier years.

[6] Preliminary.

---

[1] Where changes in boundary have occurred, averages are estimates for territory within present boundaries.
[2] Three-year average.
[3] Four-year average.
[4] Includes maslin.
[5] One year only.
[6] The estimate for the five-year period, 1909–1913, given in this table is somewhat larger than the figure obtained by averaging those five years in Table 79. This is because in the detailed table estimates for warring countries are for post-war boundaries, whereas in Table 79 they are for pre-war territory. As a result in excluding Russia, which lost territory during the war, a smaller area is excluded in the detailed table than in Table 79.
[7] Two-year average.

TABLE 78.—*Barley: Acreage, yield per acre, and production in specified countries, average 1909–1913, 1921–1925, annual 1924–1926*—Continued

| Country | Acreage | | | | | Yield per acre | | | | | Production | | | | |

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture except as otherwise stated. Estimates given are for crops harvested during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere.

[1] Where changes in boundary have occurred, averages are estimates for territory within present boundaries.

[2] Three-year average.

[3] Four-year average.

[4] One year only.

[5] The estimate for the five-year period, 1909-1913, given in this table is somewhat larger than the figure obtained by averaging those five years in Table 79. This is because in the detailed table estimates for warring countries are for post-war boundries, whereas in Table 79 they are for pre-war territory. As a result in excluding Russia, which lost territory during the war, a smaller area is excluded in the detailed table than in Table 79.

[6] Excludes native locations which produced 38,550 bushels in 1917-18 and 29,056 bushels in 1920-21.

## TABLE 79.—*Barley: World production, 1909–1926*

| Year | Production in countries reporting all years | World production excluding Russia, preliminary estimate | European total excluding Russia, preliminary estimate | Selected countries | | | | | |

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture except as otherwise stated. For each year is shown the production during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere. Estimates of world barley production for the period 1894–1908 appear in Agriculture Yearbook, 1924, p. 635.

[1] Includes all Russian territory reporting for years named.

[2] Total Russian Empire exclusive of the 10 Vistula Provinces of Russian Poland and the Province of Batum in Transcaucasia.

[3] Exclusive of Russian Poland, Lithuania, parts of present Latvia and Ukraine and two Provinces of Transcaucasia.

[4] Estimated production within present boundaries of the Union of Socialist Soviet Republics excluding Turkestan, Transcaucasia, and the Far East, which regions in 1924 produced 20,897,000 bushels.

[5] New boundaries and therefore not comparable with earlier years.

[6] Preliminary.

Division of Crop and Livestock Estimates and Division of Statistical and Historical Research. Compiled from Foreign Commerce and Navigation of the United States, 1909–1918, and June issues of Monthly Summary of Foreign Commerce, 1919–1926. Figures in italics are census returns.

[1] Based on farm price Dec. 1.

[2] Oil converted to seed on basis of 7½ pounds to a gallon and 2½ gallons of oil to the bushel.

[3] 3-year average.

[4] Not separately reported except for 1 year.

[5] Not separately reported.

[6] Less than 500 bushels for the 6 months ended Dec. 31, 1922; not separately reported since that date.

[7] Represents domestic oil only. Exports of "foreign" linseed oil not separately reported since December, 1922, but included with exports of "other vegetable oils (foreign), not elsewhere specified." Exports of "foreign" linseed oil for the 6 months ended Dec. 31, 1922, were the equivalent of 360 bushels of flaxseed.

[8] Preliminary.

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture except as otherwise stated. Estimate given are for crops harvested during the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere with the exception of India. See note on India.

[1] Where changes in boundary have occurred averages are estimates for territory within present boundaries.

[2] Three-year average.

[3] Four-year average.

[4] Two-year average.

[5] One year only.

[7] Acreage figures are for area sown. Figures of area harvested are not available for all years but official figures for 2 years and semiofficial figures for 14 years show an average harvested area 10 per cent below the sown area, although the percentage varies widely from year to year.

[8] Excludes a few minor producing countries for which no statistics are available and which do not enter into world trade. No figures are included for Germany, whose acreage in 1913 was 37,800 acres and has now fallen from 118,000 acres in 1921 to 54,900 in 1926. No production figures are available.

Division of Crop and Livestock Estimates. Figures in italics are census returns.

[1] Based upon farm price Dec. 1.

[2] Commerce and Navigation of United States, 1909–1918, and the June issue of Monthly Summaries of Foreign Commerce, 1919–1926. Domestic exports here include also shipments from the United States to Porto Rico and Hawaii; net imports are total imports minus reexports. Bushels are computed from pounds as reported in original by assuming 1 bushel of rough rice to yield 27⅞ pounds of cleaned rice.

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture. Yield has not been calculated when total acreage is below 15,000 acres. Acreage and production figures in most cases are for crops harvested in the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere.

[1] One year only.
[2] Four-year average.
[4] Two-year average.
[5] Three-year average.
[7] Less than 500.
[9] Pre-war average.
[10] Total area estimated from increase in acreage under the summer or main crop which is 88 per cent. This is probably due to an increase in the authorized area.
[11] Rough estimate of total production obtained by multiplying estimated area by average yield for five years, 1921-1925.
[12] European Turkey included.
[13] Second estimate of area 1926 is 76,632,000 acres compared with 78,496,000, the revised second estimate for 1925 or a decrease of 2.4 per cent.
[14] Year 1923. Normal crop is estimated to be about 53,200,000,000 pounds according to the China Year Book.
[15] Total area estimated from that reported in Annam, Cochin China, Laos, and first crop in Tonkin, which aggregates 9,516,200 acres compared with 9,345,700 in 1925. The area under rice in these Provinces of Indo-China in 1925 was 74.6 per cent of the total area under rice in that country in 1925.
[16] Rough estimate of total production obtained by multiplying estimated acreage by yield per acre in Provinces reporting production so far for 1926, or 623 pounds.
[17] Rough estimate for nonirrigated rice.
[18] Unofficial estimates of the Chinese crop are as follows: 70,219,000,000 pounds in 1917; 52,788,000,000 in 1920; and 50,056,000,000 in 1923.

Division of Statistical and Historical Research. The figures for each year include the crop harvested in the Northern Hemisphere within the calendar year and the following harvest in the Southern Hemisphere. Estimates of world rice production for the period 1900–1909 appear in Agriculture Yearbook, 1924, p. 653.

[1] Countries reporting from 1909 to date include India, Japan, Java and Madura, Formosa, Italy, Spain, and Dutch Guiana.

[2] Revised figures based on additional information since the publication of the 1924 Yearbook of the United States Department of Agriculture due principally to changes in the figures for Java and Madura and Siam.

[3] China would rank among the chief producing countries, but owing to lack of official statistics has been omitted.

[4] Irrigated rice. The changes in the figures for Java and Madura from those previously reported are based on official information recently received as to the percentage of cleaned rice obtained from paddy and rough rice.

[5] Estimated figures obtained by multiplying acreage under rice as classified for revenue purposes up to 1912 and acreage as reported by the Department of Land and Agriculture from 1912 on by an average yield for the years 1920–1923 for which years official estimates have been published of areas, yield, and total production.

[6] Rough preliminary estimate.

Division of Statistical and Historical Research. Official sources except where otherwise noted.

Mostly cleaned rice. Under rice is included paddy, unhulled, rough, cleaned, polished, broken, and cargo rice, in addition to rice flour and meal. Rice bran is not included. Rough rice, or paddy, where specifically reported, has been reduced to terms of cleaned rice at the ratio of 162 pounds of rough or unhulled to 100 pounds of cleaned. "Rice, other than whole or cleaned rice," in the returns of the United Kingdom is not considered paddy, since the chief sources of supply indicate that it is practically all hulled rice. Cargo rice, a mixture of hulled and unhulled, is included without being reduced to terms of cleaned. Broken rice and rice flour and meal are taken without being reduced to terms of whole cleaned rice.

Division of Statistical and Historical Research. Compiled from Daily Market Report of Division of Fruits and Vegetables. Average prices as shown are based on stock of good merchantable quality and condition; they are simple averages of daily range of selling prices. Since all varieties are included, these figures can be taken only as an index of the changes in the level of apple price.

[1] Quotations began on Sept. 1 in 1920, 1922, 1923, 1925; Sept. 7, 1921; Sept. 2, 1924; July 14, 1926.

[2] Last reported quotations of seasons May 28, 1921; May 1, 1922; May 12, 1923; June 8, 1924; Apr. 15, 1925; May 29, 1926.

---

[1] The figures in this table of production include fruit consumed on farms, sold locally, and used for manufacturing purposes, as well as that shipped. The figures do not include fruit which ripened on the trees but which was destroyed by freezing or storms prior to picking. For California the figures relate to the crop produced from the bloom of the year shown, fruiting through the winter and through the spring and summer of the following year, being picked from Nov. 1 of the year shown to Oct. 31 of the following year. Fruit not picked until after the latter date is included with the crop of the following year. For all States except California the estimates include all fruit picked after about Sept. 1 of the year shown.

[2] Including tangerines.

[3] Data from census reports.

[4] As estimated from prospects on Dec. 1.

[5] Less than 500 boxes.

### TABLE 134.—*Production and shipments of citrus fruits, by States, 1889, 1899, 1909, 1919–1926*—Continued

Division of Crop and Livestock Estimates.

[2] Including tangerines.

[6] For California the figures represent the estimated quantities shipped by rail, including quantities moved in mixed cars or by express. For Florida the figures include also that part of the crop shipped or to be shipped by boat. For both States the figures relate to the crop from the bloom of the year shown, as explained in footnote 1.

Division of Crops and Livestock Estimates.

[1] The figures shown are approximate only. They are intended to represent the numbers of citrus trees on farms and old enough to produce fruit in the year shown. The figures no doubt include some small trees producing a negligible quantity of fruit. The enumerators of the 1910 and 1920 censuses asked for orange trees and also for other subtropical fruits. In this table tangerine trees have been included with other orange trees. The enumerators of the 1925 census asked only for the number of orange trees, and the figures may include only part of the tangerine trees. In addition to the numbers shown there are in some sections a considerable number of trees on properties that were not listed as farms by the Census Bureau.

[2] Including tangerine trees.

[3] Data from census reports.

[4] From records of the Division of Crop and Livestock Estimates.

[5] Less than 500 trees.

[6] Report of 1925 census not yet available.

Division of Statistical and Historical Research. Compiled from Daily Market Report of Division of Fruits and Vegetables. Average prices as shown are based on stock of good merchantable quality and condition; they are simple averages of daily range of selling prices. In some cases conversions have been made from larger to smaller units or vice versa, in order to obtain comparability.

Earlier data for cities showing prices for 1925-26 are available in 1925 Yearbook, p. 896, Table 230.

[1] Unless otherwise stated, quotations are on bulk per ton sales.

[2] The season during which Danish cabbage prices are obtainable usually runs from October to March of the following year.

[3] Sacked per ton delivered.

[4] Converted from hundredweight price.

[5] Bulk per hundredweight.

[6] Car-lot sales.

Division of Statistical and Historical Research. Compiled from reports of Division of Fruits and Vegetables. Shipments as shown in car lots include those by boat reduced to car-lot basis.

[1] Crop movement season extends from Apr. 1 of one year through July of the following year, except in Florida, where the season begins in March.
[2] Preliminary.
[3] Includes 8 cars in August, 1923.
[4] Includes 1 car in February, 1922.
[5] Includes 28 cars in February, 1925.
[6] Includes 2 cars in February, 1926.
[7] Includes 32 cars in March, 1921.
[8] Includes 11 cars in March, 1925.
[9] Includes 3 cars in March, 1926.
[10] Includes 1 car in February, 1922 and 8 in August, 1923.
[11] Includes 28 cars in February and 11 in March, 1925.
[12] Includes 2 cars in February and 3 in March, 1926.

Division of Statistical and Historical Research. Compiled from reports of Division of Fruits and Vegetables. Shipments as shown in car lots include those by boat reduced to car-lot basis.

Shipments for 1920-1923 are available in 1925 Yearbook, p. 921, Table 271.

[1] Crop movement season extends from April 1 of one year through July of the following year, except in Florida, where the season begins in March.
[2] Subject to revision.
[3] Includes 11 cars from Florida in March, 1920.
[6] Includes 105 cars from Florida and 32 cars from Texas in March, 1921.
[7] Includes 1 car in February and 221 in March from Florida in 1922.
[8] Includes 8 cars from Michigan in August, 1923.
[9] Includes 222 cars from Florida in February and March, 1922, and 8 cars from Michigan in August, 1923.
[10] Includes 36 cars from Florida in March, 1923.
[11] Includes 109 cars from Florida in March, 1924
[12] Includes 98 cars in February; 373 cars from Florida and 11 cars from Texas in March, 1925.
[13] Includes 2 cars from Florida in February; 32 from Florida and 3 from Texas in March, 1926.

Division of Statistical and Historical Research. Compiled from Daily Market Report of Division of Fruits and Vegetables. Average prices as shown are based on stock of U. S. No. 1 grade, they are simple averages of daily range of selling prices. In some cases conversions were made from larger to smaller units or vice versa, in order to obtain comparability.

Earlier data for cities showing prices 1925–1926 are available in 1925 Yearbook, p. 927, Table 275.

---

[1] Crop movement season extends from April of one year through May of the following year, with irregular quotations continuing through June and July.

[2] Car-lot sales.

Division of Statistical and Historical Research. Compiled from reports of Division of Fruits and Vegetables. Shipments as shown in car lots include these by boat reduced to car-lot basis.

[1] Crop movement season extends from July 1 of one year through June of the following year.
[2] Preliminary.
[3] Figures for certain States include shipments in July of succeeding crop year as follows: New Jersey—1920, 15 cars; 1922, 4 cars; 1924, 4 cars; Arkansas—1921, 1 car; Kentucky—1921, 1 car; New Mexico—1921, 5 cars; Tennessee—1921, 17 cars; 1924, 3 cars; 1925, 11 cars.
[4] Florida includes 2 cars in June, 1922.

Division of Statistical and Historical Research. Compiled from Daily Market Report of Division of Fruits and Vegetables

Average prices as shown are based on stock of good merchantable quality and condition; they are simply averages of daily range of selling prices. In some cases conversions have been made from larger to smaller units or vice versa, in order to obtain comparability.

Data for 1920-1924, for cities showing prices for 1925-1926 are available in 1925 Yearbook, p. 934, Table 288.

[1] Quotations began Aug. 23, 1920 and 1921; Sept 1, 1922; Sept. 18, 1923, Sept. 2, 1924; Aug. 25, 1925; Aug. 16, 1926

[2] Last reported quotations of season May 26, 1921 and 1922, May 4, 1923; Apr. 15, 1924; Apr. 3, 1925; Apr. 16, 1926.

[3] Kiln dried.

Division of Crop and Livestock Estimates. Compiled from reports of Bureau of the Census; quantities are given in running bales, except that round bales are counted as half bales. Linters not included.

[1] Includes cotton ginned after Jan. 16 and estimated quantities not ginned on Mar. 1. Quantities in Table 321 converted from running bales, average weight, by deducting average weight of bagging and ties, by States.

[2] Sept. 16.

[3] Preliminary.

Division of Statistical and Historical Research. Official sources except where otherwise noted. Bales of 500 pounds gross weight or 478 pounds net. The figures for cotton refer to ginned and unginned cotton and linters, but not to mill waste, cotton batting, scarto (Egyptian and Sudan). Wherever unginned cotton has been separately stated in the original reports it has been reduced to ginned cotton in this statement at the ratio of 3 pounds unginned to 1 pound ginned.

[1] Less than 500 bales.
[2] Year ended Dec. 31.
[3] International Crop Report and Agricultural Statistics.
[4] Sea trade only.
[5] Eleven months.
[6] Three-year average.
[7] Two months.

Division of Statistical and Historical Research: Official sources and International Institute of Agriculture except as otherwise stated. Production figures are for the crop harvested in the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere.

[1] Figures for Europe are estimates for present boundaries.
[2] British Columbia.
[3] Two-year average.
[4] Principal producing States.
[5] One year only.
[6] Four-year average.
[7] Unofficial.
[8] Average yield in six European countries.
[9] Three-year average.
[10] Rough estimate of production for one year based on acreage for that year and yields in later years.
[11] Average yield in six European countries and the United States.
[12] Exclusive of acreage and production in minor producing countries, for which no data are available.

TABLE 294.—*Hops: Acreage, production, imports, exports, and consumption in the United States, 1910–1926*

| Year beginning July | Acreage | Production | Imports | Exports | | Consumption by brewers[1] |

Division of Statistical and Historical Research. Official sources except where otherwise noted. Includes shelled and unshelled, assuming the peanuts to be unshelled unless otherwise stated. When shelled nuts were reported, they have been reduced to terms of unshelled at the ratio of 3 pounds unshelled to 2 pounds shelled.

[1] International Yearbook of Agricultural Statistics.
[2] Java and Madura only.
[3] Less than 500 pounds.
[4] Two-year average.
[5] International Institute of Agriculture, Oleaginous Products and Vegetable Oils.
[6] Three-year average.
[7] One year only.
[8] Six months.
[9] Reports include some sesamum.

Division of Crops and Livestock Estimates.

[1] Acreage and production of beets are credited to the State in which the beets are made into sugar. Year shown is that in which beets were grown. Sugar making campaign extends into succeeding year.

[2] The planted acreage is that covered by factory-contract agreements and understandings, all of which is not actually planted by growers. Therefore abandonment may not mean actual loss of acreage.

[3] Preliminary.

Division of Crop and Livestock Estimates.

[1] Acreage and production of beets are credited to the State in which the beets are made into sugar. Year shown is that in which beets were grown. Sugar-making campaign extends into succeeding year.

[2] Based upon weight of beets sliced, except possibly in a very few factories.

[3] Percentage of sucrose (pure sugar) in the total soluble solids of the beets.

[4] Percentage of sucrose actually extracted by factories.

[5] Percentage of sucrose (based upon weight of beets) remaining in molasses and pulp.

[6] Preliminary.

Division of Crop and Livestock Estimates.

[1] Sugar campaign, usually not ended before February following season of growth of cane.

[2] One ton of sugar as made is assumed to be equivalent to 0.932 ton of refined as tentatively recommended by the joint committee on sugar statistics of the Department of Commerce and the Department of Agriculture.

[3] Figures for molasses, 1911-1914, are as reported by the Louisiana Sugar Planters' Association; figures for later years as reported by Division of Crop and Livestock Estimates.

[4] Preliminary.

[1] Beet and cane sugar only.

[2] Duty free, from Hawaii, Porto Rico, and the Philippine Islands (Virgin Islands included 1917 and subsequently.

[3] No account taken of sugar imported in other forms. Imports from the Philippine Islands excluded, reexports deducted

[4] Shipments to Hawaii and Porto Rico included. Direct exports to foreign countries from Hawaii and Porto Rico excluded

[5] Sugar used in the manufacture of other commodoties for export on which drawback was paid.

[6] No account taken of stocks at the beginning or end of year.

[7] Raw sugar converted to refined by multiplying by the following factors. Cuba and Hawaii, 0.9358; Porto Rico, 0.9393; Philippines, 0.95; All others (Santo Domingo, British West Indies, Louisiana, etc.) 0.932.

---

[1] Figures for European countries are estimates for present boundaries.

[2] Principal producing States.

[3] Two-year average.

[4] Three-year average.

[5] Four-year average.

[6] One year only, 1912-13. According to statistics of the German Sugar Association the 1912-13 sugar-beet acreage and production was greater than any other year with the exception of production in 1913-14.

[7] No sugar was produced in Bulgaria in 1925. The beets produced were probably shipped to neighboring countries for sugar manufacture or used for other purposes.

[8] No sugar beets grown in Finland prior to 1918.

[9] Exclusive of acreage and production in minor producing countries for which no data are available.

Division of Statistical and Historical Research. Estimated world total sugar production for the period 1895–96 to 1908–1909 in Agriculture Yearbook, 1924, p. 808.

[1] Figures are for the crop years 1909–10 to 1926–27 for the countries in which the sugar harvesting begins in the fall months and is completed during the following calendar year except in the cane-sugar producing countries where the season begins in May or June and is completed in the same calendar year. Production in these countries is for the calendar years 1909 to 1926.

[2] The figures quoted are the production of gur, a low grade of sugar which is mostly consumed by the natives.

[3] All grades of sugar reduced to terms of head sugar

[4] Figures for 1909–10 to 1917–18 are for pre-war boundaries.

[5] Bohemia, Moravia, and Silesia only.

[6] Preliminary.

TABLE 313.—*Sugar: Production in specified countries, average 1909–10 to 1913–14, 1921–22 to 1925–26, annual 1924–25 to 1926–27*

[1] Figures for Europe are estimates for present boundaries.

[2] Refined sugar in terms of raw.

[3] Unofficial estimate.

[4] Two-year average.

[5] One year only 1912–13. According to statistics of the German Sugar Association the 1912–13 sugar production was greater than any other year.

TABLE 313.—*Sugar: Production in specified countries, average 1909–10 to 1913–14, 1921–22 to 1925–26, annual 1924–25 to 1926–27*—Continued

[3] Unofficial estimate.

[6] No sugar produced.

[7] Four-year average.

[8] One year only.

[9] This average is larger than the 1909–10 to 1913–14 average of the figures quoted in Table 312, which refer to pre-war boundaries. The difference is mostly accounted for by the figure for Germany which in this table is an official figure for present boundaries for one year only, a year of an unusually large crop. See footnote 6. For pre-war boundaries as reported in Table 312 official figures are available for all five years. The balance of the difference is accounted for by the change in territory in Russia.

[10] Exclusive of production in minor producing countries, for which no data are available.

[11] Too small to report.

[12] Figures for the total crop are not yet available. Trade reports place the 1925–26 commercial crop at 488,000 short tons, and the 1926–27 crop at 582,000 short tons.

Division of Statistical and Historical Research. Official sources and International Institute of Agriculture except as otherwise stated. Figures are for the crop years 1909–10 to 1926–27 for the countries in which the sugar harvesting season begins in the fall months and is completed during the following calendar years, except in the case of cane-sugar producing countries where the season begins in May or June and is completed in the same calendar year. Production in these countries is for the calendar years 1909 to 1926.

[3] Unofficial estimate.
[10] Exclusive of production in minor producing countries, for which no data are available.
[13] Three-year average.

Division of Crop and Livestock Estimates.

[2] These 10 States produced 97 per cent of the maple sugar and 97.1 per cent of the maple sirup made in the United States in 1919 as reported by the Bureau of the Census. That bureau also reported 98.1 per cent of the trees tapped in 1919 as being in these States. (11 States including Connecticut from 1917 to 1923, inclusive.)

Division of Hay, Feed, and Seed. Compiled mainly from data of the seed laboratory, Bureau of Plant Industry.

[1] Imports of perennial and Italian rye grass and hairy vetch up to and including 1917, and sweet clover for all years, are based on information furnished by United States Customs Service. All other figures represent imports of seed permitted entry under the Federal seed act (formerly designated the seed importation act).

[2] Less than 500 pounds.

[3] Figures missing.

Division of Crop and Livestock Estimates.

NOTE.—The prices and values shown for 1926 are preliminary and subject to revision. In some districts, notably those of western Kentucky and Tennessee, so few sales have been made that the ultimate trend of prices for the sales season is conjectural. Prices shown for 1925 are average for the season.

Division of Statistical and Historical Research Official sources and International Institute of Agriculture except as otherwise stated Figures refer to the crop harvested in the calendar year in the Northern Hemisphere and the succeeding harvest in the Southern Hemisphere

[3] Less than 500 acres
[4] Three-year average
[5] Uuofficial estimate.
[6] One year only.
[7] Four-year average
[8] Rough unofficial estimate of annual production.
[9] Unofficial estimate for production in British India
[10] Cultivation by Europeans only
[11] These figures include a rough estimate of the crop produced by natives on the basis of an average yield of 4 piculs per bouw (311 pounds per acre), as quoted by former Trade Commissioner J. F. Van Wickel, Batavia, Java To this figure is added the official estimate of production by Europeans.
[12] No reliable data are available on production in India or China. The acreage devoted to tobacco in India would indicate a production next to that of the United States in the size of the crop. China is also of considerable importance.

---

[1] Average for five-year period if available, otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[2] Revised estimated of Division of Crop and Livestock Estimates, 1921-1926. These figures are made on the basis of census figures of 1920 and 1925, of annual assessment data, and other information. The estimates prepared in the Bureau of Animal Industry by adjustment of the census figures to a Jan. 1 basis, and including all animals in towns and villages as well as on farms and ranges are as follows: Average, 58,900,000; 1921, 67,200,000; 1922, 67,700,000; 1923, 68,900,000; 1924, 68,200,000; and 1925, 66,600,000.

[3] The number of cattle on Jan. 1, 1927, is officially estimated at 57,521,000. No 1927 column has been added as so few estimates are available for that year up to date.

[4] Year 1902.

[5] Incomplete.

[6] Year 1918.

[7] Year 1908.

[8] Countries reporting as of December have been considered as of Jan. 1 of the following year, i. e., figures for number of cattle in France as of Dec. 31, 1920, have been put in the 1921 column.

[9] Year 1920.

[10] These totals include interpolations for a few countries not reporting each year and rough estimates for some others.

---

[1] Average for five-year period if available, otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[2] The number of cattle on Jan. 1, 1927, is officially estimated at 57,521,000. No 1927 column has been added as so few estimates are available for that year up to date

[6] Year 1918.

[7] Year 1908.

[8] Countries reporting as of December have been considered as of Jan. 1 of the following year, i. e., figures for number of cattle in France as of Dec. 31, 1920, have been put in the 1921 column.

[9] Year 1920.

[10] These totals include interpolations for a few countries not reporting each year and rough estimates for some others.

[11] Unofficial.

[12] Year 1917.

[13] Buffaloes included.

[14] Year 1916.

[15] Pre-war figure census, June, 1914. Annual official estimates for 1921 and 1922 as follows: 1921, 27,943,000 and 1922, 28,138,000. These figures have not been used in table as 1922 census showed such a large increase that these estimates are probably too low.

[16] Numbers in rural communities only.

[17] September.

[18] Year 1906.

[19] No census was made as of December, 1923, which estimate would have been considered as of January, 1924, in this table, as explained in Note 8, so the figure for October, 1923, has been used.

[20] The number on Dec. 1, 1926, is officially estimated at 17,195,000. This would be placed in a 1922 column, as explained in Note 8. This column has not been added as so few figures are available for 1977 as yet.

[1] Average for five-year period if available, otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[8] Countries reporting as of December have been considered as of Jan. 1 of the following year, i. e., figures for number of cattle in France as of Dec. 31, 1920, have been put in the 1921 column.

[9] Year 1920.

[10] These totals include interpolations for a few countries not reporting each year and rough estimates for some others.

[11] Unofficial.

[13] Buffaloes included.

[21] Excludes southern territory, where there were 15,580 cattle in 1923.

[22] In addition there were 832,163 buffaloes in pre-war times.

[23] Includes 2,048,000 cattle reported in Turkestan and Azerbaijan (part of Transcaucasia) in 1920. Exclusive of this territory the number for the different years are as follows: 1921, 7,067,000; 1922, 5,230,000; and 1923, 8,227,000.

[24] Includes 3,822,600 in Turkestan and Transcaucasia in 1924. Excluding this territory the number in 1924 is 10,247,000.

Division of Statistical and Historical Research.

Figures prior to July, 1920, for good beef steers, and prior to June, 1918, for calves, compiled from Chicago Drovers Journal Yearbook; subsequent figures compiled from data of the reporting service of the Division of Livestock, Meats, and Wool. Prices for cattle, 1900-1908, and for calves, 1901-1908, are available in 1924 Yearbook, p. 855, Table 451.

[1] Bulk of sales, 1,100 pounds up. July 1, 1925 classification changed to 1,100-1,500 pounds.

Division of Statistical and Historical Research. Calculated from quotations in the Review of the River Plate. Prices prior to May, 1924, originally quoted on basis of price per head supplemented from 1916 by price per pound of dressed carcass weight. Calculations assume average dressed weight of 730 pounds or live weight of 1,259 pounds. Live-weight quotations per pound from May, 1924. Converted from Argentine currency at average monthly rate of exchange.

Bureau of Animal Industry.

---

[1] Accredited-herd work begun 1917; area work, 1921.

[2] Includes area work in units smaller than counties.

[3] Record of number of cattle included in accredited-herd work figures.

[4] No testing in 1926.

[5] Part of one county.

[6] Four towns.

[7] Testing in 1917 before work was organized by States.

[1] Average for 5-year period if available; otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[2] Revised estimates of Division of Crop and Livestock Estimates 1921-1926. These figures are made on the basis of census figures of 1920 and 1925, of annual assessment data and other information. The estimates prepared in the Bureau of Animal Industry by adjustment of the census figures to a Jan. 1 basis and including all animals in towns and villages as well as on farms and ranges are as follows: Average, 59,300,000; 1921, 58,600,000; 1922, 60,900,000; 1923, 71,500,000; 1924, 69,100,000; 1925, 56,700,000.

[3] The number of swine on Jan. 1, 1927, is officially estimated at 52,536,000.

[4] Year 1902.

[5] Incomplete.

[6] These totals include interpolations for a few countries not reporting each year and rough estimates for some others.

[7] Year 1920.

[8] Year 1908.

[9] Year 1916.

[10] Countries reporting as of December have been considered as of Jan. 1 of the following year—i. e., figures for number of swine in France as of Dec. 31, 1920, has been put in 1921 column.

[11] Pre-war figure census for June, 1914. Annual official estimates for 1921 and 1922 are as follows: 1921, 3,237,000, and 1922, 3,221,000. As the 1922 census shows a large decrease compared with 1914, these figures have not been used in the table.

[12] Number in rural communities.

[13] September.

[14] Year 1906.

[15] Year 1918. Estimated for present boundaries. The number within former boundaries on Apr. 6, 1918, amounted to 2,338,926.

[16] No census was made in December, 1923, which estimate would have been considered as of January, 1924, in this table, as explained in the note 10, so the figure for October, 1923 has been used.

[17] The number on Dec. 1, 1926, is officially estimated at 19,412,000. This would be placed in the 1927 column, as explained in the note 10. This column has not been added, as so few estimates are available as yet.

---

[1] Average for 5-year period if available; otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the figures are estimated for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[6] These totals include interpolations for a few countries not reporting each year and rough estimates for some others.

[10] Countries reporting as of December have been considered as of Jan. 1 of the following year—i. e., figures for number of swine in France as of Dec. 31, 1920, has been put in 1921 column.

[18] Unofficial.

[19] Includes 103,000 reported in Turkestan and Azerbaijan (part of Transcaucasia) in 1920. Excluding this territory, the numbers are as follows: 1921, 2,068,000; 1922, 936,000; 1923, 1,201,000.

[20] Includes 469,500 reported in Turkestan and Transcaucasia in 1924. Excluding this territory, the number is 2,196,000.

[1] Total pigs saved divided by sows farrowed as reported by farmers.
[2] Intentions are as of the close of the preceding 6-month period: e. g., those for spring farrowing, 1927 were intentions expressed as of Dec. 1, 1926.
[3] States, Ohio to Kansas, not including North Dakota.

Division of Statistical and Historical Research. Prior to 1915 receipts compiled from yearbooks of stockyard companies; subsequent figures compiled from data of the reporting service of the Division of Livestock, Meats, and Wool. Receipts, 1900–1908, are available in 1924 Yearbook, p. 902, Table 500.

[1] Figures not available prior to 1915.

TABLE 407.—*Hogs: Receipts at all public stockyards, 1915–1926*

[Thousands—i. e., 000 omitted]

| Year | Jan. | Feb. | Mar. | Apr. | May | June | July | Aug. | Sept. | Oct. | Nov. | Dec. | Total |

[1] Average for 5-year period, if available. Otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[2] Revised estimates of the Division of Crop and Livestock Estimates 1921–1926. The number of sheep on Jan. 1, 1927, is officially estimated at 41,909,000. No 1927 column has been added, as so few estimates are available for that year, as yet. These figures are made on the basis of census figures for 1920 and 1925, of annual assessment data and other information. The estimates prepared in the Bureau of Animal Industry by adjustment of the census figures to a Jan. 1 basis and including all animals in towns and villages as well as on farms and ranges are as follows: Average, 58,900,000; 1921, 67,200,000; 1922, 67,700,000; 1923, 68,900,000; 1924, 68,200,000; and 1925, 66,600,000.

[3] Year 1902.

[4] These totals include countries with less than 100,000, interpolations for a few countries not reporting each year, and rough estimates for some others.

[5] Year 1916.

[6] Year 1920.

[7] Year 1908.

[8] Countries reporting as of December have been considered as of Jan. 1 of following year; i. e., figure for number of sheep in France as of Dec. 31, 1920 have been put in 1921 column.

[9] Year 1915.

[10] June, 1914. Official estimates for 1921 and 1922 are as follows: 1921, 45,996,000; 1922, 46,134,000. These figures indicate an increase compared with 1914, while census for 1922 shows a decrease, so the annual estimates have not been used in this table.

[11] In rural communities only.

[12] September.

[13] Year 1906.

---

[1] Average for 5-year period, if available. Otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[4] These totals include countries with less than 100,000, interpolations for a few countries not reporting each year, and rough estimates for some others.

[6] Year 1920.

[8] Countries reporting as of December have been considered as of Jan. 1 of following year; i. e., figure for number of sheep in France as of Dec. 31, 1920 have been put in 1921 column.

[9] Year 1915.

[16] No census was made as of December, 1923, which estimate would have been considered as of January, 1924, in this table, as explained in note 8, so the figure for October, 1923, has been used.

[17] Unofficial.

[18] Goats included.

[19] Incomplete.

TABLE 431.—*Sheep: Number in countries having 100,000 and over, pre-war and years 1921–1926*—Continued

Division of Statistical and Historical Research. Census returns are in italics; other returns are in roman.

[1] Average for 5-year period, if available. Otherwise for any year or years within this period except as otherwise stated. In countries having changed boundaries the pre-war figures are estimates for one year only of numbers within present boundaries. For the pre-war average the years immediately preceding the war have been used.

[4] These totals include countries with less than 100,000, interpolations for a few countries not reporting each year, and rough estimates for some others.

[8] Countries reporting as of December have been considered as of Jan. 1 of following year; i. e., figure for number of sheep in France as of Dec. 31, 1920, have been put in 1921 column.

[17] Unofficial.

[18] Goats included.

[20] Sheep 1 year old and over. It is stated that 30 per cent may be added for those under that age.

[21] Includes 6,406,000 sheep and goats estimated to be in Turkestan and Azerbaijan (part of Transcaucasia) according to census of 1920. Excluding Turkestan and Azerbaijan, the numbers in Asiatic Russia for these years are as follows: 1921, 10,950,000; 1922, 6,963,000.

[22] Includes 8,887,400 sheep and goats in Turkestan and Transcaucasia in 1924.

[23] Estimates according to revised method of estimating in Australia. The revised estimate for Jan. 1, 1926, is 5 per cent greater than the figure obtained by the old method.

Division of Crop and Livestock Estimates.

---

[1] In States where sheep are shorn twice a year this figure covers wool per head of sheep shorn and not weight per fleece.

[2] Preliminary.

---

[1] Average for years 1909–1913 wherever possible, otherwise for any year or years within or near this period for which statistics are available.

[2] Estimated for total wool clip on basis of number of sheep and lambs in June, 1926.

[3] Unofficial estimate based on increase in number of sheep and lambs slaughtered.

[4] Average 1909–1913, 1923, and 1924 export calendar years. Estimate for 1925 and 1926 furnished by commercial attaché, Sept. 18, 1926, and Consul O. Gaylord Marsh, Oct. 7, 1926.

[5] Average 1909–1913. Estimates furnished by Consul Henry Robertson from La Prensa of Aug. 18, 1919. Also published in "The Economic Development of the Argentine Republic in Last Fifty Years," 1919, by Ernesto Tornquist & Co. (Figures based on exports and domestic consumption.) Year 1923, Ministry of Agriculture, Mar. 20, 1924; year 1924, official exports October to September, 1924-25, stocks and estimated domestic consumption; year 1925, exports October-September from Review of River Plate, stocks and domestic consumption (official exports for last few months not available); year 1926, estimate based on estimate for 1925 and information furnished by Assistant Commercial Attaché H. B. MacKensie, Oct. 20, 1926, indicating an increase in production of about 8,000 bales over 1925.

[6] Estimates of Yorkshire Observer. These have been used instead of official figures as comparable estimates are available for all years.

[7] Estimates for present territory based on official statistics for years 1909–1913; year 1924, official estimate from L'Economie de L'Union des R. S. S. 1925, p 290; other years based on numbers of sheep and average weight of fleece; 1926, based on information from Economic Life, Nov. 3, 1926, that procurement of wool in Russia in 1926 is 1 per cent below 1925.

Division of Statistical and Historical Research.

In this table the main object has been to ascertain the correct trend of wool production in recent years compared with pre-war in the world and in the separate countries. Estimates for all years are for present boundaries. In compiling this table a careful study has been made of estimates and methods of estimating used by the United States Department of Agriculture in compiling the world wool production for the years 1901-1906 published in the Yearbook for 1908 which forms the basis of many estimates used by the United States Department of Commerce and the National Association of Wool Manufacturers in compiling their world wool tables since that date. Careful attention has also been given to the estimates of these last two agencies. Official estimates have been used wherever available. In most cases these official estimates are not actual censuses but estimates obtained by multiplying the number of sheep on hand at a given date by a more or less accurate average weight of fleece per sheep and per lamb, which may or may not have been determined by commercial experience, and in some cases include estimates for pulled wool that is, wool obtained from slaughtered sheep. Comparatively few countries publish official estimates. In the absence of official estimates the commercial estimates as furnished by agricultural or commercial representatives of the United States in foreign countries have been used. These not being available, estimates for some countries have been obtained by using exports alone, or exports, stocks, and domestic consumption. For other countries estimates have been obtained by multiplying the number of sheep on hand by an average weight per fleece as obtained from official sources or from United States Government representatives abroad. The trend of wool production is assumed to follow in general that of sheep as there is probably not a very great variation in the average weight of fleece from year to year except in countries having great climatic changes.

[7] Estimates for present territory based on official statistics for years 1909–1913; year 1924, official estimate from L'Economie de L'Union des R. S. S. 1925, p. 200, other years based on numbers of sheep and average weight of fleece; 1926, based on information from Economic Life, Nov. 3, 1926, that procurement of wool in Russia in 1926 is 1 per cent below 1925.

[8] Small amount now produced in European Turkey included. Estimates of wool production based on official sheep and wool data for 1907 and 1909 and average weight of fleece. A rough approximate estimate for present boundaries prewar has been obtained by subtracting production in territory lost in Balkan war of 1913 and the World War. Other production figures based on estimate of the number of sheep in the territory.

[9] Exports of sheeps' wool only.

[10] Official estimate according to revised method of estimating wool production in Australia, obtained from Quarterly Summary of Australian Statistics, June, 1926, and also reported by the Australian correspondent of the Manchester Guardian, Sept. 23, 1926, p. 397. In 1924, for which year both estimates are available, this is an increase of 5 per cent over figure obtained by old method.

[11] Estimates furnished by Australian correspondent to the Manchester Guardian, Sept. 23, 1926, p. 397, who states that they are reliable estimates obtained from official sources and based on new method of estimating. In his statement they are compared with the revised 1924 figure as officially published. Losses in Queensland are taken into account in making 1926 estimate.

[12] These totals include revised estimates for Australia according to new method of making estimates of wool production. The revision in Australia in 1924 increased production for that year 5 per cent. If the figures for previous years were raised 5 per cent, then 36,000,000 pounds would be added to the 1909–1913 average and 30,000,000 to 1923.

Division of Statistical and Historical Research. Compiled from Foreign Commerce and Navigation of the United States, 1900–1918, and Monthly Summary of Foreign Commerce of the United States, June issues 1921–1926.

Cottonseed oil has been reduced to gallons at the rate of 7.5 pounds per gallon. It is assumed that 1 barrel of cornmeal is the product of 4 bushels of corn, 18 pounds of oatmeal the product of 1 bushel of oats, 1 barrel of rye flour the product of 6 bushels of rye, and 1.1 bushels of malt the product of 1 bushel of barley. The following factors have been used for converting flour into terms of wheat: 1900–1908, 1 barrel flour is the product of 4.75 bushels of grain; 1909–1917, 4.7 bushels; 1918 and 1919, 4.5 bushels, 1920, 4.6 bushels; 1921–1926, 4.7 bushels.

Boxed apples have been reduced to barrels at the rate of 3 boxes to the barrel.

---

[1] Total so far as ascertainable.

[2] Includes canned, cured, and fresh beef, oleo oil, oleo stock, oleomargarine, tallow, and stearin from animal fats.

[3] Reported in value only.

[4] Preliminary.

[5] Contains oleomargarine of animal or vegetable fats.

[6] Includes canned, fresh, salted, or pickled pork, lard, neutral lard, lard oil, bacon, and hams.

[7] Bales of 500 pounds gross.

[8] Includes barley flour 1919–1922. Barley flour not separately reported prior to 1919 or in 1923–1926.

[9] Includes "Stems, trimmings, and scrap tobacco."

[10] Includes maple sugar.

Division of Statistical and Historical Research. Compiled from Foreign Commerce and Navigation of the United States, 1900–1918, and Monthly Summary of Foreign Commerce of the United States, June issues, 1921–1926.

[1] Includes "Silk, raw or as reeled from cocoon," "Silk waste," and "Silk cocoons."

[2] Reported in value only.

[3] Three-year average.

[4] Preliminary.

[5] The following conversion factors were used in reducing flour to terms of wheat: 1900–1908, 4.75 bushels; 1909–1917, 4.7 bushels; 1918 and 1919, 4.5 bushels; 1920, 4.6 bushels; 1921–1926, 4.7 bushels.

[6] Unshelled almonds converted to terms of shelled on the basis of 30 per cent unshelled equals shelled.

[7] Unshelled peanuts converted to terms of shelled on the basis of 3 pounds of unshelled equals 2 pounds shelled.

[8] Unshelled walnuts converted to terms of shelled on the basis of 42 per cent unshelled equals shelled.

[9] Included with "All other nuts."

[10] Two-year average.

[11] Included with "All other, fixed or expressed" vegetable oils.

[12] Included with "All other, fixed or expressed" vegetable oils, 1905–1906, and "Nut oil, or oil of nuts," 1907–1909.

[13] Included with "Nut oil, or oil of nuts."

[14] Does not include "dutiable" coconut oil.

Division of Crop and Livestock Estimates.

[1] Does not include nursery or greenhouse products or forest products of the farm.

[2] The crops included are corn, wheat, oats, barley, rye, buckwheat, flaxseed, rice, potatoes, sweet potatoes, all hay, tobacco, lint cotton, beans, broomcorn, grain sorghums, hops, oranges, clover seed, peanuts, cranberries, and apples.

[3] Based upon the relation of the value of all crops to that of the 22 crops shown by the census in 1919.

Division of Farm Management and Costs. Computed from reports of owner operators (15,103 in 1924 and 15,330 in 1925) and other information. In computing this table certain arbitrary assumptions are explicitly or implicitly made. For 1922 see Agriculture Yearbook, 1924, p. 1132. For 1923 see Agriculture Yearbook, 1925, p. 1343.

[1] Averages of estimates made by 13,753 farms for 1924; by 13,948 for 1925.

[2] Averages of estimates made by 12,133 farms for 1924; by 12,811 for 1925.

[3] Based on the reported value of farm property Jan. 1.

[4] Many recall paying more than 6 per cent.

[5] Assumes that all unpaid family labor shared the reduced amount according to the amount of its claim established: (1) For the operator, as 12 times the monthly wages of hired help without board, and (2) for the rest of the family, the difference between operator's labor so figured and the reported value of unpaid labor.

[6] The assumption is that the operator bears all the burden of failure to earn common hired-labor wages and attributes such wages to his family before computing his remainder or wages.

Division of Farm Management and Costs. From returns to mail inquiry sent to crop reporters. Figures for 1923 and 1924, see Agriculture Yearbooks, 1924, p. 1134, and 1925, p. 1326.

[1] Includes miscellaneous labor, irrigating and water, seed treatment, and material.

[2] Sacks and twine, crop insurance, use of implements, use of storage buildings, and overhead.

[3] The total includes 22 reports from the following States in which there were not enough reports to show State averages: Maine, Vermont, Delaware, New Mexico, and Nevada.

TABLE 510.—*Wheat: Cost of production, by yield groups, 1925*

| Yield group (bushels per acre) | Number of reports | Average acreage in wheat per farm | Average yield per acre | Gross cost per acre: Prepare and plant | Gross cost per acre: Harvest and thresh | Gross cost per acre: Market | Gross cost per acre: Miscellaneous labor [1] | Gross cost per acre: Fertilizer and manure | Gross cost per acre: Seed | Gross cost per acre: Land rent | Gross cost per acre: Miscellaneous costs [2] | Gross cost per acre: Total | Credit per acre (straw) | Net cost: Per acre | Net cost: Per bushel |

Division of Farm Management and Costs. From returns to mail inquiry sent to crop reporters. Figures for 1923 and 1924, see Agricultural Yearbooks, 1924, p. 1136, and 1925, p. 1330.

[1] Includes miscellaneous labor, irrigating, and water.

[2] Sacks and twine, crop insurance, use of implements, use of storage buildings, and overhead.

[3] The total includes 68 records from the following States in which there were not enough reports to show State averages: Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, Utah, and California.

## TABLE 513.—*Corn: Cost of production, by yield groups, 1925*

| Yield group (bushels per acre) | Number of reports | Average acreage in corn per farm | Average yield per acre | Gross cost per acre | | | | | | | | | | Credit per acre (stover and fodder) | Net cost | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | Prepare and plant | Cultivate | Harvest | Market | Miscellaneous labor [1] | Fertilizer and manure | Seed | Land rent | Miscellaneous costs [2] | Total | | Per acre | Per bushel |
| | | *Acres* | *Bush.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* | *Dolls.* |

Division of Farm Management and Costs. From returns to mail inquiry sent to crop reporters. Figures for 1923 and 1924, see Agriculture Yearbooks, 1924, p. 1138, and 1925, p. 1334.

[1] Includes miscellaneous labor, irrigating and water, seed treatment, and material.

[2] Sacks and twine, crop insurance, use of implements, use of storage buildings, and overhead.

[3] The total includes 18 records from the following States in which there were not enough reports to show State averages: New Hampshire, Connecticut, Florida, Louisiana, New Mexico, and Nevada.

Division of Crop and Livestock Estimates.

[1] Yearly averages are from reports by crop reporters, giving average wages for the year in their localities.

[2] This column has significance only as an essential step in computing the wage index.

[3] Years 1866 to 1878 in gold.

[4] 1877 or 1878, 1878 or 1879 (combined).

[5] Weighted average quarterly, April (weight 1), July (weight 5), October (weight 5), and January, 1925 (weight 1).

Census Bureau.

[1] The farm population, as reported for 1925, comprises all persons living on farms. As reported for 1920, farm population included not only all persons living on farms, but in addition those farm laborers and their families who, while not living on farms, did live outside any incorporated place. The number thus included is believed to be relatively small. The estimated farm population for 1910 is comparable with that of 1920.

[2] The 1925 figures for Georgia and Texas and the United States total are preliminary and subject to correction.

### TABLE 541.—*Per cent rural and urban population of total population for the decades 1710–1920; urban, including all places of 8,000 and more; rural, comprising the remainder*

| Decade beginning— | Rural | Urban |
|---|---|---|

[1] Preliminary.

[2] Reported "Harrows, rollers, and pulverizers."

[3] Reported as "Cultivators and weeders."

[4] The sales statistics for 1921 relate exclusively to complete machines and were compiled almost wholly from returns made by 427 establishments classified in the "agricultural implements" industry. No sales data were collected for that year from establishments manufacturing gas tractors, horse-drawn vehicles, barn equipment, and miscellaneous farm equipment.

[5] Reported as "Farm tractors and traction engines."

Division of Statistical and Historical Research. Data for 1920 compiled from reports of the Bureau of Public Roads. Data for 1921-1924 compiled from reports of the Bureau of the Census.

[1] Preliminary.

[4] The sales statistics for 1921 relate exclusively to complete machines and were compiled almost wholly from returns made by 427 establishments classified in the "agricultural implements" industry. No sales data were collected for that year from establishments manufacturing gas tractors, horse-drawn vehicles, barn equipment, and miscellaneous farm equipment.

[6] Figures for 1921 relate to barn equipment only. No data for 1920.

Division of Statistical and Historical Research.

These relatives are based on the average of the monthly rates in effect during the crop year. Rates in effect in 1913 equal 100.

[1] These rates in effect up to Feb. 21, 1927.

[2] Based on local rates from Larimore, Leal, Makota, N. Dak., Groton, S. Dak., Scobey, Mont., and Osakis, Minn., to Minneapolis, Minn. The same rates apply to Duluth except from Groton, S. Dak., and Osakis, Minn. No proportional rates available.

[3] Based on local rates from Colfax, Wash., to Portland, Oreg., Moscow, Idaho, to Seattle, Wash., and Pendleton, Oreg., to Portland, Oreg. No export rates available.

[4] Based on local rates from Minden, Nebr., Wray, Colo., Brewster, Kans., Great Bend, Kans., Hutchinson, Kans., and Cherokee, Okla., to Kansas City, Mo.; Marshall, Mo., to St. Louis, Mo.; LaPrairie, Ill., to St. Louis, Mo.; and export rates from Wichita, Kans., to Galveston, Tex.; and Enid, Okla., to New Orleans, La.

[5] Based on all rates named in note 4 except the rate from LaPrairie, Ill., to St. Louis, Mo.

[6] Based on all rates named in note 4 except rate from LaPrairie, Ill., to St. Louis, Mo., and the export rates from Wichita, Kans., to Galveston, Tex., and Enid, Okla., to New Orleans, La.

TABLE 551.—*Livestock: Index numbers of freight rates from representative points in producing regions in the United States to their terminal markets, 1913–1925*

| Kind of livestock and district | 1913 | 1914 | 1915 | 1916 | 1917 | 1918 | 1919 | 1920 | 1921 | 1922 | 1923 | 1924 | 1925[1] |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Cattle:[2] | | | | | | | | | | | | | |
| Western district | 100.0 | 99.9 | 100.2 | 100.2 | 100.9 | 125.6 | 127.9 | 165.6 | 164.4 | 155.4 | 154.8 | 152.9 | 152.5 |
| Eastern district | 100.0 | 103.5 | 108.3 | 113.2 | 116.2 | 157.6 | 157.4 | 207.2 | 210.9 | 197.5 | 200.7 | 199.4 | 199.4 |
| Southern district | 100.0 | 100.0 | 98.9 | 97.7 | 98.1 | 120.3 | 120.3 | 148.1 | 146.8 | 136.9 | 130.0 | 130.0 | 130.0 |
| United States | 100.0 | 100.4 | 101.2 | 101.7 | 102.7 | 129.4 | 131.3 | 170.2 | 169.6 | 160.0 | 159.7 | 158.0 | 157.6 |

Division of Statistical and Historical Research.

These relatives are based on the average of the monthly rates in effect during the crop year. Rates in effect in 1913 equal 100.

[1] These rates in effect up to Aug. 1, 1926, for hogs and sheep and July 21, 1926, for cattle.

[2] Based on local rates as follows:

*Western district.*—Lanark, Ill., Lancaster, Wis., Hampton, Iowa, and Miles City, Mont., to Chicago; Fort Collins, Colo., to Denver; Salisbury, Mo., to East St. Louis; Midland, Tex., to Fort Worth; Carrolton, Mo., Bazaar, Kans., and Hereford, Tex., to Kansas City; Lancaster, Wis., to Milwaukee; Lawton, Okla., to Oklahoma City; Harlan, Iowa, and Hyannis, Nebr., to Omaha; Tarkio, Mo., and Oberlin, Kans., to St. Joe; Fergus Falls, Minn., and Hettinger, N. Dak., to St. Paul; Belle Fourche, S. Dak., and Sibley, Iowa, to Sioux City; Ashland, Kans., and Mulhall, Okla., to Wichita; Red Bluff, Calif., to San Francisco; Denver to Sidney, Nebr., and Longmont, Colo.; Kansas City to Marysville, Kans., and Gallatin, Mo.; Omaha to Atlantic, Iowa, and Schuyler, Nebr.; Sioux City to Sheldon, Iowa; Wichita to Eureka, Kans.

*Eastern district.*—Bad Axe, Mich., and Dansville, N. Y., to Buffalo; Belle Fontaine, Ohio, to Cleveland; Cass City, Mich., to Detroit; Taylorville, Ill., to East St. Louis; Hillsboro, Ind., to Indianapolis; Chicago to Jersey City; London, Ohio, to Pittsburgh; Chicago to Rantoul, Ill.; East St. Louis to Charleston, Ill.

*Southern district.*—Winchester, Ky., to Cincinnati; Port Gibson, Miss., to East St. Louis; Bowling Green, Ky., to Louisville; Pulaski, Tenn., to Nashville, Tenn.

[3] Based on local rates as follows:

*Western district.*—Lanark, Ill., Lancaster, Wis., and Marshalltown, Iowa, to Chicago; Centerville, Iowa, Shelbyville, Mo., and Parsons, Kans., to East St. Louis; Nevada, Mo., Red Cloud, Nebr., and Belleville, Kans., to Kansas City; Schleswig, Iowa, and York, Nebr., to Omaha; Maryville, Mo., to St. Joe; Fergus Falls, Minn., Cumberland, Wis., and Jamestown, N. Dak., to St. Paul; Lawton, Okla., to Oklahoma City; Hartley, Iowa. Wessington, S. Dak., to Sioux City; Herrington, Kans., to Wichita; Columbus, Wis., to Milwaukee; Hoyt, S. Dak., to Sioux Falls; Sheldon, Iowa, to Mason City, Iowa; Longmont, to Denver; Paducah to Fort Worth.

*Eastern district.*—Argos, Ind., to Buffalo; St. Johns, Mich., to Detroit; Kenton, Ohio, to Cleveland; Butlerville, Ind., to Cincinnati; Mendon, Ill., to East St. Louis; Westphalia, Ind., and Charleston, Ill., to Indianapolis; Washington Court House, Ohio, to Pittsburgh.

[4] Based on local rates as follows:

*Western district.*—Bedford, Iowa, Fort Collins, Colo., and Idaho Falls, Idaho, to Chicago; Fort Collins, Colo., to Denver; Wagon Mound, N. Mex., and Soda Springs, Idaho, to Denver; Mexico, Mo., to East St. Louis; San Angelo, Tex., to Fort Worth; Emporia, Kans., to Kansas City; Gooding, Idaho, to Ogden;

Ill.; Denver to Fort Collins, Colo., and Beaver City, Nebr.; St. Joe to Bethany, Mo.

*Eastern district.*—Chelsea, Mich., to Buffalo; Danville, Ill., to Chicago; Upper Sandusky, Ohio, to Cleveland; Marshall, Mich., to Detroit; Chicago to Dexter, Mich.

TABLE 552.—*Average weight per carload of freight originating on Class I railroads in the United States, 1920–1926*

| Commodity | 1920 | 1921 | 1922 | 1923 | 1924 | 1925 | 1926 [1] |
|---|---|---|---|---|---|---|---|
| | *Short tons* | *Short tons* | *Short tons* | *Short tons* | *Short tons* | *Short tons* | *Short tons* |
| Wheat | 40.21 | 39.89 | 40.17 | 40.35 | 40.78 | 40.93 | 41.71 |
| Corn | 36.45 | 38.07 | 38.38 | 37.88 | 37.57 | 37.31 | 38.06 |
| Oats | 31.20 | 30.55 | 30.07 | 31.04 | 31.52 | 32.00 | 30.23 |

Division of Statistical and Historical Research. Compiled from reports of the International Institute of Agriculture, except as otherwise indicated. The above rates were originally quoted in shillings; conversions made on the basis of the average monthly rate of exchange, except when exchange was at par.

[1] Average of North Atlantic ports, including New York.
[2] New York to Liverpool.
[3] From U. S. Shipping Board.
[4] Average of North Pacific ports.
[5] Rates from April to November, 1926, are from port of Montreal to Liverpool; rates for other months in 1926 and for all of 1925 are from Atlantic ports of Canada to United Kingdom.

TABLE 554.—*Fertilizer and fertilizer materials: Production and value, in the United States, 1923–1925*

| Item | Quantity |  |  | Value |  |  |
|---|---|---|---|---|---|---|

| **Pyrites produced** | 181,628 | 160,696 | 170,061 | 661,000 | 645,262 | 650,448 |

Division of Statistical and Historical Research. Compiled from annual reports of the American Fertilizer Handbook; Bureau of Mines, and the Geological Survey. Figures for earlier years appear in previous issues of the Yearbook.

[1] The northern scrap is mostly acid, while that of the Chesapeake is dry scrap; in other districts acid and dried are produced in about equal quantities.

[2] Included in "Other States."

[3] Porto Rico included, 1923–1925, and Hawaii, 1924–25.

[4] Totals include some chemical lime in Wisconsin and nonspecified States.

[5] Production for all purposes. Peat produced for agricultural purposes represented 99.6 per cent of total production in 1924 and 94.4 per cent in 1923.

[6] Includes brown rock from Kentucky.

[7] Blue and brown rock from Tennessee and brown rock from Kentucky.

Division of Statistical and Historical Research. Prices compiled from weekly quotations, Oil, Paint, and Drug Reporter. New York prices, except as otherwise stated. Values from annual reports of the Geological Survey and Bureau of Mines. Figures for earlier years appear in previous issues of the Yearbook.

[1] Converted from price of ingredient content.
[2] 16 per cent ammonia.
[3] 11 per cent ammonia, 15 per cent bone phosphate.
[4] Brown rock of Kentucky included.
[5] Blue and brown rock of Tennessee and Kentucky.

Division of Statistical and Historical Research. Compiled from annual reports of the Bureau of the Census, Bureau of Mines, Bureau of Foreign and Domestic Commerce, Geological Survey, and the American Fertilizer Handbook. Figures for earlier years appear in previous issues of the Yearbook.

[1] Subject to revision.
[2] Production plus imports for consumption minus domestic exports.
[3] Fertilizer establishments only.
[4] Imports for all purposes.
[5] Quantity sold as acid phosphate or used in the manufacture of other fertilizers.
[6] Includes ashes (wood), beet root, other potash-bearing substances (alunite, leucite, etc.) used for fertilizer.

## TABLE 557.—*Guano: Imports into the United States, 1909–1926*

Bureau of Public Roads.

[1] Superhighways (four or more lane concrete) and dual type roads included below as noted.
[2] Includes 4.8 miles of patent "rawhide" road.
[3] System increased by 1,577 miles of various types from county roads.
[4] Estimated, as State does not segregate mileage of earth, gravel, and waterbound macadam.
[5] Includes 9.7 miles of rock base only.
[6] Includes 3.7 miles dual type (two strips concrete 10 feet wide and 8 feet of bituminous macadam in center).
[7] Includes about 13 miles of superhighway 128 feet wide, two-lane concrete pavement 44 feet wide separated by 40-foot width electric railway tracks.
[8] System increased by 102 miles from county roads.
[9] Includes 205.5 miles, 9 feet wide concrete and 7 feet wide gravel.
[10] Oiled sand.
[11] Excludes 60.2 miles built by compact with towns of over 2,500 population; also system increased (by legislation) 652.1 miles of State-aid roads and 61.6 miles from counties.
[12] System increased by 259.7 miles from county roads.
[13] System increased by legislature, adding 2,640 miles (mostly unimproved) from county roads.
[14] Includes 59.9 miles dual type (24 and 27 feet wide).
[15] Partial estimate as sheet asphalt reported with bituminous concrete.
[16] Excludes Cuyahoga County four-lane super highway; not State road.
[17] Includes 12.9 miles dual type (10 to 20 foot center width surface treated macadam with two outside 10-foot widths of reinforced cement concrete).
[18] System increased by legislature with 224.6 miles of unimproved county roads.
[19] Earth road oiled for 4 miles.
[20] Includes 12.4 miles of stone base only.
[21] Includes 643.1 miles of selected top-soil mostly sand-clay.
[22] Includes 44.7 miles of Kentucky rock (asphalt) road.
[23] Data based on new surveys made.

## TABLE 561.—*Mileage of county and local roads at the end of 1925*

| State | Grand total mileage rural roads other than State highway system | Unimproved and earth partially graded | Earth to established grade and drained | Total miles of road surfaced | Sand-clay | Gravel, etc., untreated | Water-bound macadam, untreated | Surface-treated macadam and gravel | Bituminous macadam by penetration | Sheet asphalt | Bituminous concrete | Portland cement concrete | Block pavements | | | | |

Bureau of Public Roads.

[1] During year 1.577 miles of county roads were transferred to State highway system; about 370 miles were surfaced roads.
[2] Includes about 2,000 miles of sand-clay roads not previously reported.
[3] The decrease of about 7,000 miles from previously reported mileage due to a new survey by State maintenance department.
[4] Large increase in surfaced mileage, over 1924, due to corrections of survey.
[5] Includes 224 miles of traffic-bound loose rock road.
[6] During year 259.7 miles of county roads transferred to State highway system.
[7] Legislature transferred 2,640 miles of county roads to State highway system.
[8] Used data of 1921 as only available mileage.
[9] Surfaced mileage overstated in 1924; should have been 248 miles instead of 716.1 as reported.

TABLE 562.—*Gasoline taxes, 1925*

Bureau of Public Roads.

Total tax earnings on fuel for motor vehicles represent the actual taxes which are available for disposal according to the laws of the various States. The gross tax assessed and exemption refunds show the procedure for deriving the total tax, and these totals being of minor importance are not entered in this table. As some States allow no refunds for uses other than for propelling motor vehicles on highways, some of the total taxes are derived from liquid fuel, such as gasoline, etc., used for dyeing and cleaning, and for use in motor boats, farm tractors, etc., which fact should be taken into consideration. A majority of the States paid for collection costs from sources other than from this tax. The last column shows estimates based on best available data and is shown so that a fair figure for gasoline consumption may be obtainable.

[1] For maintenance only.

[2] In addition $438,436 collected on motor-oil tax of 10 cents per gallon.

[3] Includes $873,240 payments on county road and bridge bonds.

[4] Delinquent taxes uncollected not disposable in 1925.

[5] To State treasury; same partly used to pay discounts on Western & Atlantic R. R. rentals.

[6] Unaccounted for, probably delinquent taxes.

[7] Tax increased to 5 cents, effective Feb. 21, 1926.

[8] For maintenance only.

[9] Includes $282,913 for maintenance.

[10] For maintenance and reconstruction.

[11] For maintenance of Baltimore streets.

[12] Includes $3,000,000 for interest and retirement payments on State road bonds.

[13] Payments to counties on State-award highways.

[14] For sea wall in Harrison County.

[15] For State general fund.

[16] Maintenance of municipal streets.

[17] Includes $70,568 paid in delinquent taxes of former years.

[18] Covers part of first four months of year only, as new law excludes State general fund from share in gasoline-tax fund.

[19] For free school fund.

[20] Includes $460,000 payment of interest and to sinking fund on State road bonds.

[21] Tax increased to 4½ cents, effective Mar. 11, 1926.

[22] Includes $1,520,463 payment of interest on State road bonds.

[23] For improvement and repair of Washington streets.

Bureau of Public Roads.

[1] All States report amounts of full calendar year, except North Carolina, which reports for only six months, July 1, to Dec. 13 on account of the registration year beginning on July 1 in that State.

[2] The 34 States starred show complete receipt details, which are totaled below under the nine receipt columns and subtotals called "Detailed total."

[3] Total funds received by State and county officials in connection with the operation of the motor-vehicle license laws.

[4] Receipts received for registration, nonresident registrations, duplicate tags, etc., eliminated.

[5] Includes all registered vehicles.

[6] Includes $62,370 for probate judges.

[7] Amount from licenses of taxi chauffeurs allotted to State general fund.

[8] For maintenance work.

[9] No detail given.

[10] Traffic officers' expenses, deducted from county share of net receipts.

[11] All money collected deposited in United States Treasury. This amount is the appropriation for expenses of administration.

[12] Amount to balance with gross receipts. The United States appropriations for streets is much higher.

[13] Special State appropriation through State highway fund.

[14] Special State appropriation.

[15] For State highway commission maintenance.

[16] Includes $153,531 for motor-vehicle law enforcement

[17] Expenses of State highway commission.

[18] Estimated.

[19] Expenses of motor-vehicle theft department.

[20] Estimated at $302,600 paid from State appropriation.

[21] Included under motor cars.

[22] Refunds.

[23] Toll bridge commission.

[24] Collection fees of county clerks in addition to the expenses of seven city offices, $1,857,900 taken from general State fund.

[25] For period of six months, July 1 to Dec. 31, as registration year begins July 1.

[26] Interest and sinking fund requirements included in State highway amount.

[27] Special legislative appropriation of $363,659.

[28] Expenses from State highway department fund.

[29] State general fund to July 1, 1925; not to receive any share after this rate.

[30] $1,420,048 expended for administration and balance for administration of road work by State highway department.

[31] For State highway patrol.

[32] Includes $374,140 refund by amendment to law and $67,491 to State general fund.

[33] Includes amount spent on collection and administration.

[34] State appropriation of $296,969.05.

[35] Operation of auto theft law.

[36] State road commission expenses.

[37] Bond payments included with other items.

  kinds, making and use in agriculture 576
  losses 577
Phosphazote, description 548
Phosphoric acid, liquid, making and use 577–578
Photographs—
  agricultural story in, article by Reuben Brigham 578–580
  extension, requirements 579–580
  livestock, usefulness 198–201
  use in extension education 578–850
  *See also* Camera.
Picnics, farmers' 626
Piedmont region, wood-lot profits, article by E. H. Frothingham 780–782
PIEMEISEL, R. L., article on "Natural plant cover and soil potentialities" (with H. L. Shantz) 538–540
PIETERS, A. J., article on—
  "Red clover seeds' origin is important" 627–629
  "Red clover strains, how they behave" 630–631
Pig surveys—
  influence on packing business 581–582
  lung trouble, caused by roundworms 639–640
  market stabilization, article by C. L. Harlan 580–582
  methods and advantages 580–581
  *See also* Hogs.
Pima cotton, development, value, etc 252–253, 254
Pine—
  beetles, and timber conservation, discussion 162–164
  forest, Colorado, injury by grazing 386
  turpentine, chipping methods for highest yields, article by Lenthall Wyman 738–741
Pines—
  danger from gooseberry 780
  protection from blister rust 171–175
  species, menace of blister rust 173
Pink bollworm. *See* Bollworm.
PIRTLE, T. R., article on "Dairy industry in process of change" 300–302
*Pisum arvense.* *See* Peas, winter.
Plant—
  cover, natural, and soil potentialities, article by H. L. Shantz and R. L. Piemeisel 538–540
  growth—
    essential elements 504–505
    use in estimating soils 538–539
Plant Industry, Bureau, study of poisonous plants 591

Plants— Page
  foreign, asepsis for, article by Walter T. Swingle and T. Ralph Robinson ... 152-153
  poisonous to livestock—
    article by C. Dwight Marsh ... 587-591
    knowledge increase ... 498
Plowing—
  clean, value in corn-borer control ... 245
  kinds for rice ... 674-675
Plum, stocks and seeds ... 392
Plumbing, farm, article by George M. Warren ... 584-587
Poison plants—
  control measures ... 589-591
  knowledge increase ... 498
Poisoning, livestock, by plants, article by C. Dwight Marsh ... 587-591
Population—
  city, increase ... 370-371
  drift to cities, remarks ... 358
  farm—
    1925, 1920, and estimates for 1910 ... 1235
    1925 census ... 1233-1234
    estimate for January 1, 1926 ... 592
    flow to city, article by C. J. Galpin ... 591-592
    movement ... 62-63
  rural, per cent for decades 1710-1920 ... 1235
  urban, per cent for decades 1710-1920 ... 1235
Pork—
  cured, dry salt, pickled, etc., stocks ... 1108
  fresh, exports, destination, 1924-1926 ... 1184
  frozen, statistics ... 1109
  pickled, exports, destination, 1924-1926 ... 1184
  prices ... 1111
  products, statistics ... 1110

  stocks on hand, statistics ... 1108-1109
  trade, international ... 1110
Post Office Department, cooperation in hog surveys ... 580-581
Potash—
  deficiency, effect on tobacco ... 505
  German, use in United States ... 595
  importance to agriculture, article by B. E. Brown and J. J. Skinner ... 593-595
  imports previous to war ... 593
  lack, cause of cotton rust ... 594-595
  raw materials, importance ... 596
  resources, United States, article by J. W. Turrentine ... 595-597
  shortage during war ... 593
  sources in United States ... 596-597
Potassium-ammonium nitrate, description ... 548
Potato—
  seed certification, article by William Stuart ... 597-598
  supply, effect on markets, article by E. M. Daggit ... 598-599
Potatoes—
  acreage, production, value, exports, etc., United States, 1909-1926 ... 933-934
  consumption, effect of low prices and prosperity ... 598
  cost of production—
    by State groups ... 1218
    statistics ... 1217
  early, acreage, production, and prices ... 935
  exports, destination, 1924-1926 ... 1190
  fertilization with nitrogen salts ... 553
  imports, origin ... 1199
  labor requirements ... 466-467
  prices—
    paid by jobbers ... 945-946
    statistics ... 935, 944-946
  production from concentrated fertilizer, note ... 355
  seed—
    requirements ... 599
    tests ... 597
  shipments, car lot ... 939, 940-942
  statistics, production, prices, etc ... 933-946, 1190, 1199, 1217-1218
  trade, international ... 943
  world crop, acreage, yield, and production ... 936-938
  yield—
    from good seed, article by William Stuart ... 599-601

Potatoes—Continued. Page
  yield—continued.
    gain per acre ... 291-292, 294
    per acre, by States ... 935
  yields, high, prerequisites ... 600
Potts—
  C. G., article on "Sheep acres test pastures at Beltsville" ... 652-654
  R. C., article on "Butter and egg marketing methods" ... 194-196
Poultry—
  accreditation—
    influence on market, article by M. A. Jull ... 601-603
    purposes and rules ... 601-602
  breeding, etc ... 83
  diseases—
    kinds, symptoms and control ... 603-605
    prevention, article by Hubert Bunyea ... 603-605
  dressed, marketing receipts, 1920-1926 ... 1156-1161
  frozen, storage, 1916-1926 ... 1162
  industry expansion, article by R. R. Slocum ... 606-608
  marketing, trends ... 607-608
  parasites, suppression, note ... 602
  production estimates now, article by S. A. Jones ... 605-606
  statistics, prices, marketing, etc ... 1156-1162
  *See also* Chickens.
Power, farm—
  hours of work per horse ... 786-788
  tractors, use in dry farming ... 734-736
